SHIMWELL, BENJ. T., M. D., Philadelphia.
SIMON, JULES, M. D., Paris, France.
SMITH, A. A., M. D., Awkinsville, Ga.
SMITH, HENRY R., M. D., Detroit, Texas.
SOLIS-COHEN, SOLOMON, M. D., Philadelphia.
STEELE, G. M., M. D., Oshkosh, Wis.
STELWAGON, HENRY W., M. D., Philadelphia.
STEWART, JOHN S., M. D., Philadelphia.
STIMPSON, A. O., M. D., Thompson, Pa.
STOCKTON, CHAS. S., M. D., Buffalo, N. Y.
TAIT, DUDLEY, M. D., San Francisco, Cal.
TAYLOR, J. MADISON, M. D., Philadelphia.
THOMAS, G. D., M. D., Chicora, Pa.
THOMPSON, J. B., M. D., Atlantic City, N. J.
TREMINE, WM. A., M. D., Providence, R. I.
TUCKER, J. P., M. D., Overton. Texas.
TURNBULL, LAURENCE, M. D., P. H. G., Philadelphia.
TURNER, JOHN B., M. D., Philadelphia.
WALBRIDGE, L. P., M. D., Decatur, Ill.
WARD, M. B., Topeka, Kan.
WERDER, X. O., M. D., Pittsburgh, Pa.
WERNER, MARIE B., M. D., Philadelphia.
WIGHT, J. S., M. D., Brooklin, N. Y.
WILLARD, DEFORREST, M. D., Philadelphia.
WILLIAMS, CHAS. B., M. D., Philadelphia.
WILLIAMS, ROGER, M. D., Pittsburg, Pa.
WILSON, H. AUGUSTUS, M. D., Philadelphia.
WILSON, O. W., M. D., Lawrence, Kansas.
WOODHEAD, G. SIMS, M. D., London, England.
WRIGHT, ALMROTH, M. D., London, England.
ZENNER, PHILIP, M. D., Cincinnati, Ohio.

INDEX.

Abdominal section, 486 · after-treatment, 692.
Abortion, ether injection after, 316; induction of, effective method for, 315; nitric acid in criminal, 674; rapid induction with the curette. 913; threatened, opium enemata in, 112; treatment, 514; habitual, asafœtida for, 996; puerperal tetanus after, 994; tubal, 951.
Abrin and ricin in eye and other affections, 425;
Abscess, cerebral, 634; of the anterior vaginal wall, 88; of kidneys, 882; mammary, prevention of, 555; management of, 355; of the breast, 201; retro-pharyngeal, in children, treatment, 911; psoas, treatment by injections of iodoform, 992; tuberculous retro-pharyngeal, treatment, 990.
Acacia, gum of South Africa, 798.
A. C. E., mixture, 520.
Acetanilide and salicylic acid, 399.
Acetanilide for the preservation of hypodermic solutions, 278;
Acetone, reagent for, 118.
Acetonæmia, cerebral, 270.
Acetonuria in the insane, 238.
Acid, borax-boric, 238; filicic, action and uses of, 107; salicylic, as a diuretic, 40; irrigation of, in the treatment of diphtheria, 78.
Acids, fatty, in defatted cotton, 319.
"A clear statement," 840.
Actinic light, effect of fog on, 280.
Adami, J. G.—Phagocytosis, 537.
Advertisements, interleaved, 439.
Agnew, D. Hays—Obituary, 580; minute, 599.
Air in parturition, 273.
Air passages, foreign bodies in, 591; methyl violet in affections of, 425; the treatment of catarrhal affections of, 21.
Albumin in urine, test for, 675, 839, 878.
Albuminuria and nephritis, treatment of, in pregnancy, 112.
Albuminuria and renal circulation, relations between, 150.
Albuminuria, relation of to surgical operations, 232; in syphilis, 587.
Alcohol and death rates, 237.
Alcohol and nerve-centres, 371.
Alcohol and the nervous system, 116.
Alcohol, as a food, 517.
Alcoholism and tuberculosis, 918.
Alcoholic beverages, administration to children, 597.
Alcohol disease from a physiological aspect, 450.
Alcoholic injections in the treatment of reducible hernia, 151.
Alcoholic neuritis, 351.
Alkaloidal assay of narcotic plants, 158.
Alkaloids and alcohol, 999.
Allen, Mary E., M. D.—Premature baldness, 869.
Alopecia areata and trichorrhexis, 403.
Amenorrhœa in school-girls, 555.
American Electro-therapeutic Association, 760.
American Pharmaceutical Association, 119.
American Neurological Association, 999.
Americans in the Riviera, 80.
American Surgical Association, 840.
Amaurosis and albuminuria of pregnancy, 592.
Amputation of the leg under cocaine anæsthesia, 152.
Amylene, hydrate of, in epilepsy, 268.
Amylhydrate as a hypnotic, 903.
Anæsthesia, local, produced by injection of water, 66; local and general, 104; in pregnancy and diseases of women, 994.
Anæsthetic new, pental, 193, 939, 948; warm ether as, 271, 308.
Anders, Jas. M., M. D., Combined cardiac lesions, 164; epidemic influenza, 445.
Angina pectoris, 589; treatment of, by cocaine, 104, 144.
Anthrax, ipecacuanha in, 224.
Antibiotic substances, 492.
Antiperiodic, methylene-blue as, 388.
Antipyretics, hypnotic action of, 102; and pyrexia, 271; in childhood, 77.
Antipyrine in hepatic colics, 389; reaction, new, 741; to dry up the milk secretion, 593, 707; gangrene following injections of, 709; in whooping-cough, 758; in chorea, 795, 65; in affections of the pharynx and larynx, 31; in hemeralopia, 691.
Antisepsis, 315; and puerperal mortality in Paris hospitals, 240; for the hands, 753.
Antiseptics, surgical, iodine water and aristol as, 73, 438; for the Grippe, 189.
Anus, fissures of, in children, 277.
Are colds infectious? 199.
Asepsis in Von Bergman's clinic, methods of carrying out, 230.
Aortic insufficiency, two types, 750.
Aortic narrowing a new sign, 387.
Aphthæ or thrush of vulvæ, 756.
Appendicitis, medical treatment of, 84; recurring, 980.
Aristol in rhinitis, 570.
Army Medical Board, 80, 400.
Arsenical cod-liver oil, 559.
Arsenic for trichinosis, 120.
Arsenic in common life, 758. 955.
Arteries, ligation of, 433.
Arterio-sclerosis, causes of, 711.
Arthrotomy in old luxations, 70.
Arthropathies in tabes dorsalis, 721.
Artificial neurasthenia, 67.
Ashton, W. E.—Intestinal anastomosis, 565.
Asphyxia, nitro-glycerine in, 1018.
Association of American Institutions for Idiotic and Feeble-minded Children, 800.
Asthma, cocaine in, 40.
Athetosis, general, 947.
Atropia, subcutaneous injection of, as a hæmostatic, 29.
Automatism, epileptic, 100.
Azoospermia, gonorrhœa, prophylactic treatment, 633.

Bacilli, actions of phagocytes on, 491; tubercle, in the aqueous humor of cattle, 79.
Bacillian infection, 997.

Bacillus of chorea, 191, 350; of enteric fever, 33; of measles, 876; of influenza, 244; of tubercle, attenuation of, 924.
Bacteria in drinking water, 358; intrauterine transmission of, 793.
Bacteriological researches upon saliva of children suffering from measles, 156.
Bacteriology of yellow fever, 313; of endometritis, 755.
Bacterium coli communis and peritonitis from intestinal perforation, 670.
Bacteria, reaction of aqueous extract from, 719.
Baldness, causes of premature, 677, 869; congenital, 837.
Baldy, J. M., M. D.—Supra-vaginal hysterectomy, 53; chronic endometritis, 406.
Bandages, warm, hypnotic effect of, 858.
Barker, T. Ridgway, M. D.—Mooted points concerning the vomiting of pregnancy, 133; chloroform in parturition, 811.
Barr, Martin—Acute parenchymatous nephritis, 502.
Basedow's disease, 422.
Bathing, hot, in Japan, 838.
Baths, cold, in broncho-pneumonias, 960.
Bed, deadly cold, 759.
Beidert's method, shortening of, for finding tubercular bacilli in sputum, 277.
Benzine as a preventive of trichinosis, 278; in pediculosis, 268.
Benzonaphthol, 435; in uræmia, 426.
Benzosol as a substitute for creasote, 988.
Bile, secretion in biliary fistula, 429.
Binkerd, A. D.—Fracture of skull and trephining, 540; scalds and burns, 337; pneumonitis, 730.
Bismuth, vehicle for, 147; bromide of, 376; salicylate, 760.
Bladder and prostate, operations on the, 34; tumors, diagnosis of, 588.
Blair, Louis E., M. D.—Pathological conditions of nose and throat as causal factors in asthma, 166.
Blaschko, A., M. D.—Alopecia areata and trichorrhexis, 403.
Blindness, preventable, 159; temporary, during lactation, 433.
Blood-clot, importance of, in treating dead spaces, 45.
Blood in health and disease, specific gravity of, 108.
Blood in disease, specific gravity of, 228.
Blood of influenza patients, micro-organism of, 246.
Blood-poisoning, 262.
Blood and urine in the insane, 406.
Bogus American Diploma, 159.
Boils and their treatment, 858.
Bokenham, T. J.—Phagocytosis, 539.
Bone in the throat, 572, 785.

Book Reviews:

Wood, Casey A.—Eye Disease, 223.
Year-Book of Treatment, 665.

Borate of sodium in epilepsy, 819.
Borax-boric acid, 238.
Boron, pure, 879.
Brain and its membranes, contribution to the pathological anatomy of the retina and optic nerve in diseases of, 110.
Brain, bullet in for 29 years, 713.
Brain, disease following nasal operation, 590.
Brain, hydatid cysts of, 1.
Brain surgery, present status, 5, 752.
Bran, raising children on, 117.
Bread, Russian, analysis, 519.
Breast, abscesses of, 201; hypertrophy of, 995.
Breast milk, morphology of, and nutrition of the child, 117.
Bremer, L.—Modern neurology, 1005.
Bright's disease, strontium in, 425.
Bristowe, J. Syer—Phagocytosis, 525.
Bromamide, a new remedy, 790.
Bromides and increased susceptibility to infection, 633.
Bromides, actions of, 746.
Bromide of potassium, accumulation in different tissues, 746.
Bromol, 158.
Bronchitis mixtures, 543.
Broncho-pneumonia, treatment of in children, 308; cold baths in, 960.
Brown-Sequard and isopathy, 600.
Brushes, sterilization of, 109.
Buboes, treatment of, 30.

Bumping, remedy for, 279.
Burns and scalds, 337; glycerin for, 310, 180; treated by europhen, 830.
Butter, vegetable, 116.

Cæcitas syllabaris, 311.
Cæsarean section, 453, 714, 233, 154.
Cactus grandiflora, actions of, 907.
Camphor, hypodermic injection of, 192.
Camphor and thymol, hydroscopic character, 478.
Canada, physicians in, 480.
Cancer, peripheral neuritis in, 392; of the uterus, early diagnosis of, 197; primary, of the clitoris, 198; uterine, cause of recurrence, 875; of testicle, 991.
Canon, P., M. D.—Micro-organism in the blood of influenza patients, 246.
Cantharidinates, action of, 667.
Carbolic acid hypodermatically in tetanus, 466.
Carbuncles, excision of, 513, 239.
Carcinoma, of breast, 884; vaginal hysterectomy for, 235; new treatment of, 310; treatment, 986.
Cardiac grippe, 561.
Cardiac Lesions, combined, 164.
Cardiac tonics, 705.
Cardiopathies, causes, 711.
Caries of lumbar vertebræ, 608.
Caruncle, urethral, 155.
Cary, Chas.—Hemiplegia, 523.
Castor oil, testing, 165.
Cataract, simple extraction of, 88.
Catarrh, relation to laryngeal phthisis, 990.
Catgut infection in the dry treatment of wounds, 551.
Cathartics, abuse of, in gynæcological treatment, 355.
Catheterization of the female bladder, 714.
Catramine, a new terbinthinate, 907.
Cauda equina, compression of, 35.
Caustic, lunar, preservation of, 3.
Cauterization of the cervix and uterus, danger of, 114.
Cautery, actual, use in gynæcology, 474.
Cellulitis, 921.
Cephalic tetanus, 226.
Cerebral acetonæmia, 270.
Cerebral abscess, 634.
Cerebral atrophies in childhood, 595.
Cerebral localization, 910.
Cerebral surgery, present aspect of, 4, 672.
Cerebral syphilis, 350.
Cervix, chancres of, diagnosis of, 114.
Cervix, racemose sarcoma of, 235.
Chancre, hard on lip and soft on genitals, 539.
Chancroid, concealed with sloughing, 807.
Characteristics of the present pandemic of influenza, 200.
Charcot, Prof.—Intermittent claudication, 361; Arthropathies, 721.
Chaulmoogra oil in leprosy, 906.
Cheese, digestibility, 796.
Chemotaxis, 492, 493.
Chests, medical, on railroads, 471.
Chicken-pox, complications, 557.
Childbed, prurigo in, 273.
Children, young, errors in feeding, 115.
Chirography and merit, 560.
Chloral, action of Borax on, 760; as a hypnotic, 904.
Chloralamide, as a hypnotic, 383; effect of heat on, 559.
Chlorine water and quinine in typhoid fever, 465.
Chloroform, drop by drop method of administering, 458. rapid anæsthesia with, 467; in obstetrics, 592; impure, toxic effects of impure, 667.
Chlorosis, febrile, remarkable case, 908; scarification of os uteri in, 675.
Choleodochotomy, case, 590.
Cholera, ætiology and toxicology, 459.
Chorea, 262; antipyrine in, 65, 795; and epilepsy, relation between, 629; bacillus of, 191, 250; exalgin in, 594, 676.
Circumcision, endocarditis following, 505.
City dust, 276.
Class Banquet, Jefferson Medical College, 119.
Claudication, intermittent, 361; as a diagnostic sign in doubtful cases of diabetes, 909.
Clark, E. S., M. D.—Disease of the mastoid process, 770.
Clavicle, simple fractures of, suture in, 313.
Climate-therapy, cardinal truth of, 986.
Climatic treatment of phthisis at Colorado Springs, 15.
Clitoris, cancer of, 36; primary cancer of, 198.
Cobleigh, E. A., M. D.—Molluscum fibrosum, 847.
Coca, as a prophylactic against influenza, 144; East Indian, 438.
Cocaine in pertussis, 236; in treatment of angina pectoris, 144; anæsthesia in amputation of the leg, 152; in the treatment of angina pectoris, 104; laparotomy under, 715; anæsthesia in enucleation of eye, 552; poisoning, prevention of, 704, 1010; death from, 668; in peritonitis, 348.
Codeine: Its physiological action and therapeutic employment, 1005.
Cod-liver oil, arsenical, 559.
Coe, Henry C., M. D.—Examination of young girls, 761.
Coffee as an antiseptic, 1018.
Coffee-tea, 476.
Conjunctivitis, granular, new treatment of, 104.
Colchicine for the eye, 425.
Cold in treatment of yellow fever, 348.
Colic, treatment, 757; hepatic, antipyrin in, 789; sodium salicylate in, 40.
Colitis, 121.
Colotomy, indications for, 792.
Colles fracture, 283.
Color reaction for salol, 199.
Colorado Springs in the climatic treatment of phthisis, 15.
Colotomy, 922.
Coma, diabetic, case of, 297.
Composition of tuberculin, 199.
Compressed medicine to be used in the army and navy, 160.
Conjunctivitis, granular, treatment, 949.
Convulsions, tetanoid, operation for, 72; infantile frequency of, 77; tetanoid, in an infant, 607; in children, treatment of, 275; treated by compression of the carotid, 510.
Copaiba balsam as a diuretic, 550.
Coplin, W. M. L., M. D.—Strictured male urethra, 734.
Corn cures, 633.
Cornea, artificial, 872.
Cornutin as a hæmostatic in hæmorrhages from the bladder and female genitals, 103.
Corset and the stomach, 638.
Corson, Hiram, M. D.—Pneumonia and its treatment, 824.
Coryza, acute, treatment, 549.
Costotomy, 672.
Cotton, defatted, presence of fatty acids in, 319.

Electricity in metrorrhagia, 235.
Electricity in uterine fibroids, 274.
Electro-gynæcology, 323.
Electrotherapy, 263.
Empyema, remarkable case of, 312.
Eneuresis, nocturnal cured by excision of Luschka's tonsil, 875.
Enuresis, nocturnal, in mouth-breathers, 117; manual treatment, 827.
Enucleation for goitre, 62 cases of, 231.
Enfield, A., M. D.—Alcohol disease, 450.
Endocarditis following circumcision, 505.
Endometritis, treatment of, 434, 739; chronic, 406; and acute infectious diseases, 515; bacteriology, 755; puerperal, histological study of, 315; subacute, in the later months of gestation, 994.
Entozoa, prevention of spread, 797.
Epidemic influenza, re-appearance of, 270.
Epididymitis, instillations of nitrate of silver, 552.
Epileptic colonies, 957.
Epileptics, visual field in, 935.
Epilepsy, and chorea, relation between, 629; unusual manifestations of, 221; hydrate of amylene, 268; Jacksonian, electrolysis of cortex in, 633; trephining for, 635; treated by bromides and nerve sedatives, 587; relation of cerebral anæmia and hyperæmia to, 589; treated by trephining, 673; traumatic, 881; following re-vaccination, 709; influence of pregnancy on, 715; borate of sodium in, 819.
Epileptic automatism, 109.
Episcleritis, 449.
Epistaxis, an easy and effectual method of stopping, 553.
Epithelioma, 882; sulphate of magnesia in, 467.
Ergot and ergotine, actions of, 744, 830.
Ergotin subcutaneous use of, 194.
Errors in feeding of young children, 115.
Erysipelas, recurrent, 704.
Erysipelas and tuberculosis, 748.
Ether, warm, as an anæsthetic, 271, 308; subcutaneous injections of, in puerperal eclampsia, 197; local application of, in strangulated hernia, 232; does it assist digestion, 318; injection after abortion, 316; as a stimulant, 744; reaction on the urine, 919.
Etherization in laryngeal croup, 225, 317.
Etiology of hyperemesis gravidarum, 316.
Eucalypto-resorcin, 399.
Euphorin in gynæcological practice, 835.
Exalgin in chorea, 594, 676.
Examination of the eyes of the insane, 67.
Exercise in childhood and youth, 842.
Expiration of carbuncle, 239; of the liver, results of, 313; of varicosities for ulcers of leg, 313.
Eye diseases, subconjunctival injections of corrosive sublimate, 467.
Eyes of the insane, examination of, 67.

Facial hemiatrophy, 191, 311.
Facial paralysis, 910.
Fallopian tube, anatomy and physiology, 875; fibroma of, 716.
Faradization and galvanization in treatment of uterine fibroids, 240.
Farnsworth, P. J.—Opium, belladonna and chloral poisoning, 971.
Fat, effect of deep inspiration on the assimilation of, 718.
Feeble-minded, occupation, 1014.
Feeding, errors in, of young children, 115.
Fehling's solution, permanent, 838.
Female, gonorrhœa in, 35.
Femur, fracture of, results of treatment of, 314.
Fetid feet, 797.
Fever, catarrhal, treatment, 419; diet in, 558; enteric, bacillus of, 33; enteric, yeast in, 66; typhoid, treated by yeast, 147; typhoid, treatment of in children, 41; typhoid, condition of heart in, 70; typhoid, experimental, 228; typhoid, peroxide of hydrogen in, 224;

puerperal, prophylaxis of, 156; thermic, complicated by croupous pneumonia, 48; yellow, bacteriology of, 313; of growth, general considerations, 990.
Fibroids, uterine, electricity in, 274, 995.
Fibroma, diffuse, of both breasts, 873.
Fibromyoma, ætiology of, 956.
Fibrosarcoma of nasal fossæ, 675.
Fibro-sarcomatosis, 847.
Filiariosis, surgical, 471.
Fingers, cut off, union of, 272.
Fire-proofing formulæ, 799.
Fissures in the anus, 950; in children, 277.
Fistula, gastric, 353.
Fitch, C. M,, M. D.—Water as a therapeutic agent, 890.
Florand, Dr.—Treatment of diarrhœa in children, 334.
Florence redivius, 548.
Fluid with meals, 318.
Fog, effect of, on actinic light, 280; London, surgical aspects of, 711.
Forceps, obstetric, misapplication of, 434.

FORMULÆ:

Abortion, habitual, 825.
Absorbent powder, 577.
Alcoholism, strychnine in, 220.
Alopecia, following acute diseases, lotion for, 57.
Alterative, 519, 900.
Aluminum in diphtheria, 343.
Ammonia muriate in grippe, 900. Anæmia, 662.
Anæsthetic, local, 302, 382, 544.
Angina, acute, 826.
Anodyne liniment, 900.
Anticebum pill, 577.
Antisepsis, intestinal, 139.
Antiseptic adhesive ointment, 220.
Antiseptic salve, 738.
Arthritis, rheumatoid, 220.
Asthma, 24, 186, 343, 420, 662, 982.
Atony, gastro-intestinal, 24.
Baldnesss, 578, 938.
Beverage, refreshing, 1014.
Bladder, irritable, 671.
Blenorrhagia, 58.
Blister, horse, 699.
Brandreth's pills, 982.
Brandy with egg, 219.
Bronchitis, acute, 505.
Bronchitis, chronic, 700; mixtures, 543.
Burns, 982.
Cancer of uterus, disinfectant injection, 703.
Cardiac dilatation, 420, 700.
Cardiac tonic, 577.
Catarrh, nasal, 458.
Catarrh snuff, 825.
Chancroids, 554.
Chilblains, 506, 662, 981.
Chloralamide, 700.
Chloroform, compound elixir, 578.
Chlorosis, 662, 1014.
Cholelithiasis, 96.
Cod-liver oil emulsion, 577.
Cocaine, elixir, 825.
Coca, wine of, 900, 938.
Cod-liver oil, palatable, 700.
Collyrium, 500.
Comedones, 826.
Constipation in infants, 96.
Constipation, thiol in, 505.
Consumption, 544.
Coryza, 578; abortive treatment, 420; acute, 549; with anosmia, 863.
Creolin-iodoform ointment, 505.
Cough, nervous, 382.
Creasote, compound wine of, 57.
Croup, 344, 413.
Cystitis, 938; chronic, 864.
Dandruff, 577.
Dermatol, 506.
Diabetes insipidus, 828; care of teeth in, 981.
Diarrhœa, chronic with intestinal fermentation, 382; chronic, in children, 900; in children, 544; infantile, 782; mixture, 900; resorcin in, 139; 937; 1014.
Diphtheria, 826; and croup, 344; hydrochloric acid in, 662; laryngeal, 343; papoid in, 302; permanganate of potassium in, 825; topical application in, 96, 140, 1014
Depilatory, 661.
Disinfectant, intra-uterine, 506.
Diuretic remedy, 782.
Douches, nasal, 24.
Dropsy cardiac origin, 661.
Dysentery, 343; acute and chronic, 426.
Dysmenorrhœa, 937.
Dyspepsia, acid, 738; fermentive, 500; pyloric pain, 937
Dyspnœa in heart disease, 1013.
Earache, 505.
Eclampsia, 577.
Eczema, 382; acute, 262; infantile, 864; of anus and scrotum, 382; of children, 220, pruriginous, 420, 661; vulvar, 662, 987; 937, 982.
Emmenagogue, 544, 578.
Ergotine for hypodermatic injection, 420.
Erysipelas, 343, 382, 506.
Expectorants, 302, 662, 782.
Expectoration, purulent, 590.
Favus, treatment of, 262, 864.
Feet, sweating, 982.
Fever catarrhal, 419.
Fever, typhoid, treatment of, 302.
Fissures of the tongue, 96, 140.
Gargle, 96, 500.
Gastritis, acute, 343.
Gastro-intestinal catarrh, infantile, 738.
Glossitis, marginal exfoliative, 420, 782, 937.
Glottis, spasm of, 430.
Gonorrhœa, 96, 302, 408, 506.
Gout, 24, 96, 699, 864.
Grippe, hyposulphite of soda in, 644.
Gums, bleeding, 982.
Hæmatemesis, from gastric ulcer, 863.
Hæmatochyluria, bichromate of potash in, 186.
Hæmoptysis, 382, 500, 826.
Hæmorrhage, 506, 864.
Hæmorrhoids, 186, 578, 900.
Hair, falling out of, 262.
Hair wash in seborrhœa capitis, 219.
Headache, 57, 578, 981.
Heart, irritable, 220, 662.
Hemicrania, 981.
Herpes præputialis, 782.
Hiccough, 505.
Hives, 219.
Hyperchloridia, 864.
Hyperidrosis, 58, 782.
Impotence, functional, 699.
Incontinence of urine, 558, 700, 825.
Influenza, 505, 506, 644, 982; camphor in, 661; colds, 506.
Insomnia, infantile, 96.
Intestinal antisepsis, 577, 867.
Iodoform, Frey's emulsion, 900.
Irritable heart, 220.
Itching of measles, scarlet fever, etc., 900.
Jaundice, 344.
Keely cure, 382.
Kola essence, 544.
Lanoline ointments, 578.
Laryngeal affections, 140.
Laryngitis, stridulous, 782.
Laxative, 96.
Leg ulcer, 863.
Leucorrhœa, 700.
Linseed oil emulsion, 578.
Lupus erythematosus, 826.
Lupus, facial, erythematous, 863.
Malaria, 186.
Matism, 220.

Meningitis, epidemic cerebro-spinal, 58.
Menorrhagia, painful, 826.
Metrorrhagia, 738, 864.
Milk substitute, 699.
Mouth-wash, disinfectant, 661, 1014.
Muscilage, 826.
Nephritis, acute, 982
Neuralgia, 24, 343, 344, 699, 825, 863, 937.
Night-sweats, 577.
Nipples, cracked, 24, 863.
Odontalgia, 738.
Ophthalmia, scrofulous, 662.
Orchitis, 220.
Os uteri, painless dilatation of, 220.
Otalgia, 186, 544 1013.
Otitis, syphilitic, 140.
Ottorrhœa, 826.
Papoid in diphtheria, 302.
Pediculi pubis, 863.
Pelada, 96.
Peritonsillitis and tonsillitis, recurrent, 302.
Pharyngitis, chronic, 24.
Phthisis, cough, 1013.
Piperidizine, 505.
Pityriasis versicolor, 420.
Plaster of Paris, 365.
Pneumonia, grippal, 863; fibrous, 937.
Powder, dusting, 58.
Prurigo, 898.
Pruritis, 982, 1013.
Pruritis ani, 578.
Pruritis vulvæ, 420.
Psoriasis, 938.
Ptyriasis versicolor, 544.
Purgative in children, 458.
Purgative pill, 344.
Quinine, for infants, 661; hypodermic injections of, 343; solution, palatable, 458.
Rhachitis, 557.
Rheumatism, 544, 900, 1004; and lumbago, 96.
Rheumatoid arthritis, 220.
Rhinitis, scrofulous, 570.
Rickets, phosphorus in, 262.
Ringworm, 186, 343.
Round worms in children, 220
Salol as a coating for pills, 262.
Scabies, 140, 344, 738.
Sciatica, 24, 219.
Scrofula, 262.
Sea sickness, resorcin in, 699.
Seborrhœa capitis, hair wash in, 219.
Seminal emissions, 219.
Shampoo, 662.
Skin diseases, chronic, 577.
Smallpox vesicles, to prevent pitting of, 96.
Sore throat, 782.
Stomatitis, in children, 220; mercurial, 506.
Strychnine, in alcoholism, 220.
Styrone, as a deodorant, 900.
Sycosis, 826.
Syphilis, during pregnancy, treatment of, 58.
Sweating hands, treatment of, 58.
Tetanus, 343; traumatic, 826.
Throat, sore, 458.
Tonic, 544, 594, 699, 900, 937, 1013.
Tonsillitis, acute, 382, 420; chronic, 863; rapid cure, 262; and peritonsillitis, recurrent, 302.
Tuberculosis, 139, 937.
Tympanites, 738.
Typhoid fever, 302, 577.
Ulcers and gangrenous wounds, 343; chronic, fuchsine in, 140; varicose, 58.
Uterine hæmorrhage, hydrastin in, 864.
Urticaria, antipyretics in, 58.
Vaginal catarrh, acute, 738.
Vomiting, 24, 577.
Vulva, eczema of, 262.
Whooping-cough, 24, 220, 458, 544, 982.
Worms, round, in children, 220; seat, 680.
Fraenkel, A., M. D.—Multiple neuritis, 281.
Fractures and injuries of the spine, 49.
Fracture of colles, 283; of the skull, compressed, treatment, 90; of shaft of the femur, treatment of, 314.

Histories and summaries of cases, 169.
Homatropine discs in refraction, 931.
Huchard, H.—Cardiac grippe, 561; grippal pneumonia, 601; Cardio-vascular grippe, 801.
Hunter, Wm.—Phagocytosis, 526.
Human race, mortality of, 400.
Hutinel, Dr.—Cold-bath in broncho-pneumonias, 960.
Hydropathy in the treatment of diphtheria, 103.
Hydatid cysts, of the lungs, 909; of the brain, 1.
Hydatids in the pelvis stimulating ovarian tumor, 114.
Hydatiform mole, 636.
Hydrastinin, 836; in metrorrhagia, 76.
Hydrastin in uterine hæmorrhage, 701.
Hydrastis canadensis in obstetrics, 234.
Hydrate of amylene in epilepsy, 268.
Hydrazoic acid, 597.
Hydrocele, cure by excision of sac, 430; treatment, 672.
Hydrocephalus, chronic, 711.
Hydrogen peroxide, 500; antiseptic properties, 667; test for, 680; in eye diseases, 870; treatment of fistulæ by, 90; as a disinfectant of water, 936.
Hyoscine as a hypnotic in the insane, 653, 869, 904.
Hyoscyamine, as a hypnotic, 904; in lettuce, 558.
Hyperemesis gravidarium, ptyalism and hysteria, 76.
Hypnotic action of the antipyretics, 102.
Hypnotic suggestion, Onanism cured by, 666.
Hypnotics, their use among the insane, 901.
Hypnotism, 107; legal restrictions, 957.
Hypnotism and electro-magnetism, 749.
Hysterectomy, supra-vaginal, 53; vaginal, for carcinoma, 235; for carcinoma of uterus, 915.
Hysteropexie, new method, 516.
Hysterorraphy, modified, 914.
Hysteria, in children, two cases, 676; in infants and children under 2 years, 357; syphilitic, 392.
Ichthyol, 787; in pyrosis, 146; in gynæcological practice, 240, 594; new observations of therapeutic actions, 907.
Icterus in the new-born, 594.
Igni puncture, value of, in treatment of hypertrophied cervix uteri, 75.
Ileo-colostomy, 952.
Ilium, fracture of anterior superior process of, 980.
Ileus, olive oil in large doses, 510.
Importance of blood-clot in treating dead spaces, 45.
Impotence in men, treatment, 788.
Impregnation from semen deposited on the vulvæ, 273.
Inebriety, inherited, prophylaxis, 718.
Infant mortality in France, 677.
Infants, artificial feeding, 615.
Infectious diseases and endometritis, 515.
Influence of diseases upon the respiratory interchange of gases, 108.
Influenza, abroad, 160; chloride of ammonium in, 103; cerebral disturbances following, 887; and neuroses, 708; bacillus, 244; epidemic; re-appearance of, 270; laryngeal paresis after, 312; nervous and mental phenomena as sequelæ of, 297; vaccination as a prophylactic against, 198; speedy cure of, 348; insanity, 352; epidemic, 445; and pelvic cellulitis, 474; infectiousness of, 391; influence on the death-rate, 638; eye lotions of boric acid in, 558; prophylaxis and treatment, 549; treatment of, 308, 906; coca as a prophylactic against, 144; quinine as a prophylactic, 956.
Inhalation, oxygen, 30.
Inhalations of ozone in treatment of whooping-cough, 275.
Injection of ether after abortion, 316.
Insane, acetonuria in the, 238; blood and urine in, 406; hyoscine in, 633; urine toxicity of, 679.
Insanity, alleged increase, 759; an excuse for adultery, 520; and typhoid fever, 311; influenzal, 352.
Instruments, metal, sterilization of, 149.
Insufflation, happy application of, 704.
International Congress of Syphilis and Prostitution, 439.
International Dermatology Congress, 200.
International Gynæcological and Obstetrical Congress, 520, 560.
Intestinal anastomosis, 565.
Intestinal obstruction, treatment of, 269; from Meckel's diverticulum, 471; due to round worms, 512.
Intestine, nerve supply of, 191; submucous resection of, 34; pathology of nerve-plexuses, 791.
Intravenous saline infusion, 667.
Intubation, and tracheotomy, 795; of the larynx, 436; in croup, 117; in Russia, 556; in 1890-91, 156.
Inversion of non-puerperal uterus, 135.
Iodine water and aristol as surgical antiseptics, 73, 438.
Iodism, 268.
Iodoform as a prophylactic in ophthalmia neonatorum, 916.
Iodofrom gauze in postpartum hæmorrhage, 507.
Iodoform sponges, 708.
Iodol, therapeutic uses, 663.
Iodo-naphthol, 519.
Ipecacuanha in anthrax, 224.
Irrigation, intra-uterine, after labor, 197.
Iris, gumma of, 178.
Iritis, ætiology, 885.
Iron, glycerite of, 839.
Isopathy, 600.
Itching, ætiology, 946.

Jaborandi for urticaria, 224.
Jackson, Edward, M. D.—Simple extraction of cataract, 88.
Jambul in diabetes mellitis, 745.
Jefferson Medical College, new buildings, 479.
Jenkins, R. J., M. D.—Surgical knowledge in general practice, 291.
Jewett, Chas., M. D.—Cæsarian section, 453.

Kanthack, A. A.—Phagocytosis, 497.
Kelly, E. B. P., M. D.—Obituary, 26.
Kerauno-neuroses, 108.
Keyser, P. D., M. D.—Pterygium, 123.
Kidney, abscess of, 882; changes of, in phthisis, 149; disease with cardiac complications, 92; extirpation of tuberculous, 686; sarcoma of, 258; gun-shot wound, 977.
Kinnicutt, Francis P.—Prophylaxis and treatment of tuberculosis, 844.
Kirkpatrick, A. B., M. D.—Medical treatment of appendicitis, 84.
Kitasato, S., M. D.—Influenza bacillus, 245.
Klein, E.—Phagocytosis, 496; remarks on influenza bacillus.
Kneipp's water cure, 146.
Koch's remedy in minute doses, further results from, 224.
Koenig, Adolph, M. D.—Pneumonia, 651.
Kola, purified, 998.
Konig, Franz.—Hæmophilias, 999.

Labor, cutaneous emphysema during, 592; induction of by injections of glycerine, 674; premature, caused by multiple arthritis, 755; hymen obstructing, 914; pains, weak in old primiparæ, 516.
Labors, results of, 200, without internal disinfection, 913.
Lactation, temporary, blindness during, 433.
Lactic acid in diarrhœa, 427.
Lactose and glucose as diuretics, 988
La Grippe, 40; effects of on mind and nervous system, 303; specific for, 172; [See Influenza.]
Laparotomy for wounds of liver, 73; incomplete, with injury to the bladder, 724; in peritonitis, 115; under cocaine, 715.
Laparotomies, remarks on series of one hundred, 75.
Lard, test, 639.
Laryngeal croup, etherization in, 317.
Laryngeal obstruction from milk curd, death, 864.
Larangeal paresis after influenza, 312.
Larynx and pharynx, antipyrin in the affections of, 31.
Larynx, fractures of, 635.
Lavage, of stomach for hiccough, 427, in vomiting following chloroform, 29.
Law suit, curious, 799.

Multiple neuritis, 281; puerperium as a causative factor, 636.
Muscles, ocular, 352.
Mussels, urticaria of throat from eating, 468.
Mynter, Herman—Case of crushed kidney, 933.
Myositis, 481; ossifying, 512.
Myrtol, 477.
Naphthalin in whooping cough, 274, 595.
Nasal fossæ, fibrosarcoma of, 675.
Nasal septum, fracture of, 729.
Nascentium, trismus, sulfonal in, 120.
Nephrectomy, transperitoneal, 993.
Nephritis, acute parenchymatous, 502; and albuminaria, treatment of, in pregnancy, 112; latent, 454; new variety, 669; scarlatinous, prophylaxis, 676.
Nerve-grafting, 911.
Nerve-stretching in the treatment of perforating ulcer, 890; in tic douloureux, 393; therapeutic value of, 31.
Nerve supply of the intestines, 191.
Nerves, suturing of, 74, 711.
Nervous and mental phenomena and sequelæ of influenza, 207.
Nervous system and alcohol, 116.
Neuralgia, methylene blue in, 736; trigeminal, various surgical procedures for cure, 793.
Neurasthenia and changes in gastro-intestinal tube, 669; and its relations to mental diseases, 97; and varicocele, 552; artificial, 67; injections of infusions of nervous tissue in, 943.
Neuritis, alcoholic, 351; multiple, 281; peripheral, in cancer, 392.
Neurology, modern, 1005.
Neuroses, and influenza, 703; and neuro-psychoses after trauma, 589.
Newborn, obstetrical paralysis in, 113.
New Jersey State Medical Society, 905.
Nitroglycerine, subcutaneously in poisoning by illuminating gas, 194; in asphyxia, 1018.
Nitrous ether and astringent drugs, 678.
Noble, Chas. P.—Minor gynæcological surgery, 611.
Nocturnal enuresis in mouth-breathers, 117; manual treatment, 827.
North Brother Island Hospitals, management, 920.
Nose and throat, pathological conditions of, as causal factors in asthma, 166.
Nursing bottle, 876.

Obstetrical bundle, 834.
Obstetric cases, last, 100, 294.
Obstetric paralysis in the newborn, 113.
Obstetric practice: the necessity for the more general use of abdominal palpation and pelvimetry, 25.
Obstetrics and gynæcology, present status, 966.
Obstetrics, chloroform in, 592; hydrastis canadensis in, 234; tobacco in, 272.
Obesity, 919; influence of, on female sexual functions, 316.
Ocular muscles, 352.
Ocular paralysis, recurring, 792.
Œsophagus, diverticulum, 822.
Œdema as a symptom occurring in malignant diseases, 81.
Olive oil in large doses in ileus, 510; detection of peanut oil in, 437.
Onanism cured by hypnotic suggestion, 666.
Oophoritis, acute, complicating pregnancy, 515, 636.
Ophthalmia neonatorum, iodoform as a prophylactic, 916; as a cause of blindness, 129.
Ophthalmia, prevention of contagious, 783.
Opiates, contraindications for use of, 368.
Opium, alkaloidal variability of, 558; disease, new studies of, 372; enemata in threatened abortion, 112; tincture, improved, 719; belladonna and chloral poisoning, 971; strychnine as an antidote, 986.
Opticians, prescribing, 480.
Optic lobes, diagnosis of lesions of, 792.
Orexin, action of, on the stomach, 179, 309;
Organs, of hearing and life insurance, 126.
Osmic acid in goitre, 64.
Ostitis, of hip, 608; suppurative after tamponing, 647.
Ovarian cystoma, 339.
Ovaries, incomplete removal of diseased, 274; removal of for mollities ossium in non-puerperal women, 680.
Ovariotomy, 541; in a patient in her eighty-second year, 953.
Ovaritis, chronic, treatment, 396.

Ovary and tube, supernumerary, 915; colossal fibro-systoma of, 915; papillary cystoma, 515.
Ovulation without menstruation; pregnancy, 675.
Oxaluria and hæmaturia, 31.
Oxygen inhalation, 30; pure, to obtain rapidly, 158.
Ozæna, radical cure for, 111; treatment of, 267.
Ozone, inhalations of, in whooping cough, 275.

Pains of central origin, 351.
Packard, Jno., M. D.—Supra-public cystotomy, 321.
Palate, cleft, operation for, 314.

Thompson's disease, 946.
Throat and nose, pathological conditions of as casual factors in asthma, 166.
Thumb, dislocation of the end bone, 852; treatment of irreducible luxations, 470.
Thymacetin, 438, 678.
Thyme, common, in whooping-cough, 19[illegible], 317.
Thymolina, substitute for listerine, 272.
listerine, 272.
Thyroidectomy in exophthalmic goitre, 554.
Tibia, tuberculous disease of, 684.
Tic convulsiv, 469.
Tissue resistance and tissue cells, 490.
Tobacco, attempt to render harmless, 518; in obstetrics, 272.
Tocci brothers of Locana, Italy, 887.
Toes, fracture of, 923.
Tongue, pilocarpine for dryness of, 267.
Tonsillitis, contagiousness of, 998.
Tonsillotomy, etiology, prophylaxis and therapeutics of hæmorrhages after, 230.
Torticollis, acute, treatment, 788.
Toy balloon in the trachea, 954.
Transformation of virus, 358.
Trauma, neuroses and neuro-psychoses after, 589.
Tremor, hereditary, 946.
Trephining, prehistoric, 832; the vertebral column in gunshot wound of the spinal canal, 231.
Trional and tertonal in mental disease, 943.
Trichinosis, arsenic for, 120; benzine in, 278, 788.
Tricocephalus, disorders caused by, 107.
Tubercle bacilli in the aqueous humor of cattle, 79.
Tuberculin, immunity conferring principle in the blood of animals treated with, 677; composition of, 199; in laryngeal phthisis, 66; in treatment of leprosy, 744; in the treatment of lupus, 29.
Tuberculosis, and alcoholism, 918; and erysipelas, 748; dissemination in cars, 477; prophylaxis and treatment, 844; pseudo, 710; transmitted by seminal fluid, 808; hereditary, prophylactic treatment, 956.
Tuberculous infection, predisposition to, 237.
Tucker, J. P.—Perityphlitis, 936.
Tumenol, 345, 389.
Tumors and plastic operations treated by overheating the tissues, 390.
Tumors, primary, of the heart, 226; translucency of solid, 835; tuberculous laryngeal, 871; abdominal, 979; of frontal lobes, disturbance of equilibrium, 989.
Turnbull, Lawrence, M. D., P. H. G.—Organs of hearing and life insurance, 126.
Turner, John B., M. D.—Treatment of membranous croup, 412.
Tylophorine, a new emetic, 839.
Typhoid fever and salads, 837; and insanity, 311; chlorine water and quinine in, 465; chloroform in, 830; in New York, 579; peroxide of hydrogen in, 224; treatment, 586; chlorine in, 970.

Ulceration of the mouth as symptom of lead poisoning, 227.
Ulcers, method for grafting, 73; extirpation of varicosities for, 313; old, on leg, treatment of, 271; perforating, nerve stretching in, 890; varicose of leg, treatment, 432.
Umbilicus, septic disease of, 196.
Uræmia, benzonaphthol in, 426; treatment of, 65.
Uræmic coma and convulsions, treatment, 907.
Urea, action of, on the vascular walls, 107; new method of estimating, 359.
Urethra, female, prolapse, 556.
Urethra, male, ætiology and treatment of obstructions of, 734.
Urethra, stricture of, 402.
Urethral carbuncle, 825.
Urethritis, abortive treatment, 472; bichloride of mercury in, 706.
Urine, disappearance of sugar from, 670; in the insane, 406; reaction with ether, 919; test for sugar in, 477; toxicity of the insane, 679.
Urticaria, iodide of potash in, 318; jaborandi for, 224; of throat from eating mussels, 468; psoriasis and sycosis, 241.
Uterine cavity, rapid exploration of, 396.
Uterine fibroids, electricity in, 274; treatment of, by combined galvinization and faradization, 240.
Uterine hæmorrhage, rapid dilatation of uterus for, 754.
Uterus, cancer of, early diagnosis of, 197; effects of caustics on, 726, 756; extirpation of for submucous fibroid, 716; non-puerperal, inversion of, 135; pregnant, prolapse, 514; puerperal inversion of, 593; rupture, 913; rupture in early labor, 874; total extirpation of, 114; total extirpation for malignant disease, 47; rupture at the beginning of labor, 951.

Vaccination, ancient Hindoo, 677; as a prophylactic against influenza, 198; death after, 717; efficient, what is, 277; in Austria, 92.
Vagina, laceration of, 395; occlusion of, 794.
Vaginal wall, abscess of the anterior, 88.
Vapor, iodoform, in whooping-cough, 37.
Varicocele and neurasthenia, 552.
Varicola, treatment of, 72.
Varicosities, extirpation of, for ulcers of leg, 313.
Variola and vaccine, 758.
Vaseline, detection of fats mixed with, 279.
Vegetable butter, 116.
Vehicle for bismuth, 147.
Version, forceps as an aid, 952.
Vertebral column, trephining, in gunshot wound of, 231.
Vertigo, Meniere's, and semicircular canals, 67.
Vertigos, semeiology, 871.
Vienna Medical Society, 958.
Viennese custom, morbid, 400.
Vinegar, method of determining the presence of free mineral acids, 957.
Vin. iodinii comp. in the treatment of catarrhal affections of the air passages, 21.
Virus, transformation of, 358.
Viscera, movable, 225.
Visiting Nurse Society, 839, 760.
Vomiting, lavage in, following chloroform, 29; treated by blistering over vagus, 388.
Vulvo-vaginitis, in little girls, 517.

Walbridge, L. P.—Mechanical treatment of chronic rheumatism, 855.
Ward, M. B.—Protest against the carelessness in examination and treatment of female patients, 217.
Water, as a local anæsthetic hypodermatically injected, 464; as a therapeutic agent, 890; bacteriological examination of, 557; cure, Kneipp's, 146; drinking, bacteria in, 358; drinking, to test for impurities, 79.
Weather, influence on disease, 39.
Werder, X. O.—Peritonitis, 173.
Werner, Marie B.—Contraindications for use of opiates, 368.
Whooping-cough antipyrin in, 758; common thyme in, 195, 317; early symptom of, 156; inhalations of ozone, 275; iodoform vapor in the treatment of, 37; naphthalin in, 274, 595; quinine as a remedy for, 357; remedy, 638; second attack, 517.
Wight, J. S.—Bone in the throat, 572; dislocation of end bone of thumb, 852.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. PAUL GIBIER, Director of the New York Bacteriological and Pasteur Institute. "Peroxide of Hydrogen and Ozone—Their Antiseptic Properties." *Medical News* of Philadelphia, Pa.

DR. GEO. B. HOPE, Surgeon Metropolitan Throat Hospital of New York. "Some Clinical Features of Diphtheria, and the Treatment by Peroxide of Hydrogen." *New York Medical Record.*

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

Charles Marchand

☞ Mention this publication.

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS. Laboratory, 10 West Fourth St., New York.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda.

Among many points in which this preparation excels, are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830.

JOHN C. BAKER & CO., Philadelphia.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lecture.

HYDATID CYSTS OF THE BRAIN; ALTERNATE PARALYSIS (OCULO-MOTOR AND PATHETIC PARALYSIS OF THE RIGHT SIDE; HEMI-ANÆSTHESIA AND HEMIPARALYSIS OF THE LEFT SIDE); HEMIPARESIS LESS MARKED ON THE RIGHT SIDE; DOUBLE OPTIC NEURITIS.

BY PROF. DUCAMP, M. D.,
CHIEF OF THE MEDICAL CLINIC IN THE FACULTY OF MONTPELIER.

Gentlemen:—Hydatid cysts are not frequently met with in the brain. Of 363 cases of tumor of the brain recorded by Davaine only in 20 were these cysts found; and in 16 out of the 136 collected by Cobbold. Of the 40 observations made by Morgan, in 10 cases the cysts were found in the cerebral lobes, in 8 in the cerebellum, in 4 in the ventricles, in 2 in the corpus callosum and in 1 in the frontal lobes[1]. I wish now to call attention not to the rarity of the disease but to the cerebral troubles, perfectly localized and circumscribed, produced by the presence of a large hydatid tumor. I shall discuss with you the nature of these troubles.

History.—Alexandrine Devr, 17 years of age, was admitted to the St. Eloi Hospital, on the 22d of June, 1889, during the service of Castan, Sr.

Her family history showed that both father and mother, still living, are victims of rheumatism, and that a sister died at the age of 18 months, from convulsions. In regard to her individual history we learned that in childhood she suffered from cervical adenitis, and later on from a defective menstruation. The present malady began three months ago and was then only characterized by headache and constipation. A month afterwards, the patient was obliged to go to bed, owing to a moderate continuous fever, accompanied by vomiting, sharp, intestinal pain and an aggravated condition of headache and constipation. These symptoms rendered her unable to get up for a little more than a month until the young lady was taken on the 22d of June to the suburban hospital mentioned. The cephalalgia continued to increase, vomiting became much less frequent, but the constipation persisted. Fever was slight, never going above 38° C. The pulse ranged from 80 to 90.

A marked intellectual apathy was observed; paresis of the extremities came on progressively, and was especially marked on the superior extremity of the left side. The dynamometric measurement gave 19 kilogrammetres for the right and 10 kilogrammetres for the left hand. There was complete loss of sensation on the right side of the body, the same phenomenon being manifested on one half of the face.

Vision was disturbed; on both sides the visual acuteness was diminished V. O. D. G. ½. Perception of colors remained intact. On the left side a slight falling of the eyelid and external strabismus due to complete paralysis of the internal rectus muscle were observed; this latter lesion producing a crossed horizontal diplopia. The pupil was dilated but was still sensible to the action of light and to accommodation. This dilatation was increased by atropine. The right eye exhibited no external abnormal appearances.

Ophthalmoscopic examination showed more marked alterations of the left eye, an engorged disc, and tumefaction—in fact, all the characteristic signs pertaining to an optic neuritis to the typical choked disc. There were also some signs of ecchymosis.

Examination of the different organs, such as the lungs, the liver, the heart, etc., gave negative results; they were apparently healthy.

On the 6th of July the dropping of the right eyelid became considerably increased,

[1] Rabot Kyste hydatiyne du cerveau. *Progres Médical*, February 23, 1890.

ptosis being finally complete, accompanied by paralysis of the superior rectus muscle.

By the 13th, complete paralysis of all the muscles of the right eye, with the exception of the external rectus, was established, but there was no variation in the size of the pupil.

Finally, on the 15th of July the patient passed suddenly into a comatose state, the respiration became difficult, and death took place in a few hours, without there being noticed, in all the course of the disease any other alteration of the temperature or of the pulse than that mentioned. There were no convulsions, no incontinence of urine, no albuminuria, and no glycosuria.

Autopsy.—There was no inflammation of the meninges. From the moment that the brain was removed from the cranial cavity it was clearly perceived that the right hemisphere was considerably enlarged. On the external face of the right sphenoidal lobe, between the corresponding convolutions, a transparent pouch filled with fluid was found. This tumor, independent of the healthy white substance, of easy enucleation, occupied the posterior half of the sphenoidal lobe and extended to the anterior half of the occipital lobe, without affecting the cortical gray substance. The tumor was not in direct contact with the lateral ventricle nor with the internal capsule, nevertheless they exhibited signs of compression, especially marked at the internal face of the sphenoidal lobe and near the peduncle. Puncture of this sac produced in a rapid and progressive manner a diminution in the size of the right hemisphere, owing to the escape of a clear liquid resembling distilled water, the quantity of which reached 250 grammes. This liquid revealed on examination a specific gravity of 1006, but no albumen or glucose. It contained however 0.74 grammes per 100 of chloride of sodium. The sac was found to be elastic, and under the microscope exhibited no external connective tissue, but was chiefly composed of stratified fibres without any cellular elements. Over two points were noticed small opaque or whitish granular matter. The rest of the encephalic mass was healthy.

Remarks.—In the presence of this clinical case whose evolution was not entirely studied at the hospital, a diagnosis rested between a tubercular meningitis and a tumor of the brain. Although the temperature and the pulse would exclude the idea of tubercular meningitis, yet, the duration of the malady, the cephalalgia, the vomiting, the constipation, the general paralytic phenomena, and the fact that a sister of the patient had died from convulsions at the age of 18 months, all pointed to the probable existence of that inflammatory affection. The ophthalmoscopic examination alone, however, revealed to us an unmistakable sign and sustained the diagnosis of a cerebral tumor. We discovered, in fact, the presence of a choked disc, characteristic of a tumor of the brain.

True it is that tubercular meningitis produces alterations of the disc as we have had occasion to study before, but these differ so materially in their intensity, that the error of diagnosis could not have been made. Moreover, the tumor by its mere presence in the brain is alone sufficient to explain the various phenomena observed, and especially the motor disturbances which, as P. Grasset has remarked, "show from the very beginning a progressive paralysis[1]." The slight elevation of temperature can only be attributed to the state of congestion determined in the brain at the neighborhood of the tumor. Under such circumstances a correct diagnosis was extremely difficult. That of tubercular meningitis was suggested by the history of the case, by the march of the disease, and even by the signs revealed by the microscope, as the lesion might possibly have been a cerebral tumor of a tubercular nature. But if we excluded this diagnosis to what other cause could be attribed the series of phenomena presented by the case? A careful examination revealed no history of syphilis. Now, vascular tumors, glioma, sarcoma, ecchinococcus and cysticercus are antagonistic, we may so say to tubercular lesions, and out of these different hypotheses we could not formulate a correct or even reasonable diagnosis.

Finally, the anatomical signs exhibited by the ophthalmoscope added nothing to the clearing of the question and taking all into consideration, we could not but ascribe the trouble to the existence of a cerebral tumor.

The anatomical lesions however, were not sufficient, and in nervous pathology we must look for, and determine if possible, a topographical diagnosis. The predominance of paralytic disturbances on the left side, and the anæsthesia limited to the same side, indicated in a clear manner that the tumor rested largely upon the right side of the

[1] Ducamp.—Des manifestations opthalmoscopiynes de la meningite tuberculeuse. These de Montpelier, 1888.

[2] Grasset.—Traitè des maladies du systeme Nerveux.

encephalic mass. The co-existence of these motor and sensory phenomena, with alternate oculo-motor and pathetic paralysis pointed to a lesion of the cerebral peduncle. It was evident, therefore, that the tumor exercised pressure especially upon the external portion of the root of the peduncle. This alteration in the functional activity of the oculo-motor nerve, could only begin to take place in the deep portion of the peduncle at a short distance away from the anastomotic fibres of the oculo-motor of the opposite side, because the internal rectus muscle was completely paralyzed, the pupil remaining sensitive to light and retaining the power of accommodation. The dilatation of the pupil, finally, showed us that the lesion must be located at the inferior surface of the peduncle, as has been established by Blanc[1]. Again, Duval, from his anatomical researches has determined pretty well the existence of oculo-motor fibres at the superior portion of the peduncle, and therefore a pressure upon that part by the tumor could explain the progressive oculo-motor symptoms exhibited by the patient.

In regard to the paralysis of the superior oblique muscle, that was undoubtedly due to pressure exercised upon the pathetic nerve as it surrounds the external surface of the cerebral peduncle. It remains to consider whether these two cranial nerves, the origins of which are situated near each other, were not affected by a nuclear paralysis, and that the succession of paralytic symptoms could not possibly be due to lesion of the anatomical antero-posterior area, which, according to Henson and Volkers,[2] constitutes the common origin of the nerves in question. But as the internal rectus was totally paralyzed, a nuclear paralysis could not be thought of, for "in nuclear paralysis of the third pair, the movements of the third pair are abolished as regards a converging action, but are intact when the movements are to follow those of the external rectus muscle of the opposite side."[3]

It became, then, possible to establish a diagnosis of a tumor pressing upon the right side of the cerebral peduncle, upon the sensory portion and upon the motor area containing the fibres of the oculo-motor nerve, and finally upon the pathetic nerve surrounding the peduncle. This diagnosis explained the symptoms ascribed to a lesion of the right side of the encephalic mass, but it did not explain those ascribed to lesion of the left side manifested clinically in a right hemiparesis. The presence of a tumor, the character of the hemiplegia less marked than that of the opposite side, would lead us to suppose that the left side of the peduncle was also taking part in the productions of the symptoms observed, decreasing, so to speak, from right to left, and that the only portion affected was the motor area, the sensory part and the fibres of the oculo-motor nerve remaining intact.

Thus far, we are obliged to definitely admit the existence of a pressure exercised in a decreasing manner, as has been remarked, by a tumor situated on the corresponding motor area of the right side of the brain.

At the autopsy the diagnosis of these localized lesions was confirmed, but it was found that the tumor of the syheno-temporal lobe had produced its peculiar symptoms not by a direct but by an indirect pressure, and that this tumor, whose diagnosis would place it at the base of the brain, was so voluminous that it even occupied the external surface of the convolutions.

Remember that the tumor had produced sensory and motor symptoms in the extremities of both sides, and it must also be remembered that Chouppe has demonstrated that the internal capsule may be injured by cerebral tumors without producing hemianæsthesia, and that Charcot has observed a hemiplegia caused directly by a voluminous hydatid cyst.

The disassociation of the oculo-motor fibres appears perfectly clear in our case. The stage of the paralysis seems to show that the nerve fibres of the internal rectus muscle were completely paralyzed from the beginning, near the point of pressure, and more to the outside of that of the elevator muscle which was less affected. Later on, the right superior oblique muscle became paralyzed after complete paralysis of the elevator muscle, and lastly the nerve-fibres supplying other muscles lost their power. This succession of disturbances brings to our mind the divisions of Hensen and Volkers, in regard to the origin of the oculo-motor nerve. These physiologists describe, antero-posteriorly, as it were, the following centres: "the origin of the rectus internus muscle at the anterior limit of the aqueduct, above the posterior commissure; then the cellular origin of the superior rectus and of the elevator; following this, that of the inferior

[1] Le nerf moteur oculaire commun et ses paralysies. These de Paris, 1885, p. 111.

[2] Arch. d'Opht. de Græfe, XXIV.

[3] Féré. Anatomie Medicale du Systéme Nerveaux.

rectus; and lastly, still further back, that of the inferior oblique."[1]

The fibres which arise from these origins, to be distributed to the different muscles, have been examined microscopically by Kahler and Pick,[2] and these authors have divided them into two groups: an external one which contains the fibres of the elevator, the rectus superior and the inferior oblique; and a median group which contain the fibres of the rectus internus and of the rectus inferior.

Our autopsy did not seem to explain this disposition of the fibres, since the order of the paralysis was as follows: internal rectus, elevator, superior rectus, inferior rectus and inferior oblique. All clinical observations could not possibly fail to corroborate the delicate microscopical researches referred to.

In regard to the slow paralysis of the pathetic, it can only be explained by the greater resistance to pressure offered by a nerve already constituted by itself, and not dependent upon radical, disassociated fibres.

If we had left hemianæsthesia and slight hemiparesia of the right side, our case would be clinically one of left hemi-paralysis associated with crossed paralysis of the common oculo-motor, and this, anatomically, would point to a lesion of the peduncle. Benedikt[3], of Vienna, says of this lesion that it is "a syndrome characterized by a hemiparesis and a crossed paralysis of the common oculo-motor, associated with tremors of the paralyzed extremities." "In that case," as the author has remarked, "the lesion lies evidently in the cerebral peduncle on the level of the origin and exit of the oculo-motor nerve;" and further states: "The syndrome which I am studying has a great importance, since it shows a localization sufficiently clear to explain the tremors. This motor disturbance is produced in our syndrome by a lesion lying in the peduncle at the origin of the common oculo-motor nerve. In sclerosis, where the tremors resemble those of the disease under consideration, the lesion which causes it is found over the same region." Our case, which presents a change entirely peduncular, does not authorize us to recognize as yet such a localization for the tremors, although the case is different from that of Benedikt, especially in regard to disturbances of sensibility. Again, there is a little difference also, with regard to loss of sensibility, in a case reported recently by A. Manquat and Ed. Crasset,[1] in which there was hemianalgesis, the authors locating the lesion at the cerebral peduncle, a little above the origin of the oculo-motor nerve. On the other hand, in this "instance the tremors are slight and are noticed on both sides." Without wishing to contradict the statement published by the authors, we cannot but conclude that a peduncular lesion does not necessarily produce tremors.

In regard to medical treatment, whatever it may be, it could not give any good results, unless, perhaps, an external opening of the cyst could have been established. Clemenceau has seen a case of this nature, where a cure was spontaneously effected. Was surgical interference indicated? No. The tumor was not accessible, as it seemed to occupy the base of the brain, near the peduncle and without any connection with the external surface of the hemispheres. The symptoms were all peduncular and pointed to the existence of a great intracranial pressure.

Now that the malady ended in the death of the patient, we have frequently asked ourselves whether we could have agreed with Money, and allowed trephining to be performed. We mention this apropos of a communication of Webster[2] about a case of hydatid cyst of the brain, which terminated in death, in which Money expressed his opinion here referred to. We do not forget the good results that trephining has produced in several instances in the hands of Penn, Gilbert Ballet, Gelineau, Lepine, and Lucas Championiere, which have been reported to the Academy of Medicine[3], but some of those cases were of a different nature; on the other hand, when we conceive of a tumor reaching the external surface of the convolutions and apparently inbedded within them, then the gravity of the case becomes unquestionable.

In conclusion, we know that this foreign body was an acephalocyst, of considerable volume, developed in the deep portion of the white substance, without known cause, and that its development was accomplished in the course of about four months. This duration is in accordance also with the published tables of Ball and Krishaber[4] where the

greatest number of cerebral tumors is recorded, the clinical evolution of such tumors ranging from one to six months.

COMMUNICATIONS.

CLINICAL CONTRIBUTIONS TO BRAIN SURGERY.[1]

BY JOHN B. ROBERTS, M. D.,

PROFESSOR OF ANATOMY AND SURGERY IN THE PHILADELPHIA POLYCLINIC; PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PHILADELPHIA.

In 1885[2] I took strong ground in favor of more active surgical interference in injuries and diseases of the cranium and brain. At that time the views advocated by me were looked upon as being too radical, and were quite vigorously opposed by many prominent surgeons of this country. Since that date there has been developed an unprecedented activity in the operative treatment of cranial and intra-cranial lesions, which, even in my opinion, has been too extreme. It is, perhaps, not difficult to understand this unscientific and unreasonable adoption of what might be called a surgical fashion. It is to be regretted that the enthusiasm created by success impells some men to interfere surgically in nearly all cases that come into their hands without a judicious study of each particular patient. That unrestrained mania for operating which has made abdominal surgery almost a by-word has, it seems to me, entered into the domain of cerebral surgery. It is just as much a part of scientific surgery to abstain from operating unnecessarily, as it is to combat vigorously the unreasonable conservatism of those who will not see the force of anatomical, surgical, and statistical evidence. Fortunately for the patients a healthy reaction is at last taking place, and surgeons are not now removing brain centres and tunnelling the brain in search of abscesses and tumors in quite as enthusiastic a manner as they were a couple of years ago. That such lesions should be promptly attacked surgically is unquestioned, but this should be done only after a thorough survey of the conditions and a judicial estimate of the gain that will possibly arise. The experimental character of many operations upon the brain in recent years has been almost as patent as in vivisectal operations done with an avowed experimental purpose. Death on the operating table and unsuccessful operations have at length begun to stay the hands of these over-enthusiastic surgeons: and there is now ground for hope that cerebral surgery will, ere long, become less reckless.

My personal opinions are very much what they were in 1885; indeed, the advances in diagnosis and the improvements in operative methods have made me even more sure of the correctness of the conclusions then advanced. I cannot, however, bring myself to approve of the reckless way in which human life is often threatened by operations which hold out scarcely a ray of hope to the helpless patient. The rapidity of healing in aseptic wounds and the tolerance of the brain under operative attack do not justify hasty resort to intra-cranial surgery simply because the patient or his family are submissive under the persuasive eloquence of the would-be operator.

I desire to-night to report a few cases which have a practical bearing on some of the fundamental principles of cerebral surgery, and I hope they will serve as a means of bringing out the views of others in this interesting field.

CASE I.—*Trephining for cortical epilepsy apparently the result of traumatism; improvement, followed by death in five weeks.*—A child, twenty-nine months old, had sixteen months previously received a fall, and on the second day after the accident was seized with convulsions. Four months before he had been struck on the head by a falling clock, but no special symptoms followed this mishap. Since the second attack he had had spasmodic seizures occurring at frequent intervals nearly every day. He dragged the left leg a little, did not seem bright, and was still unable to talk. There was a slight tendency to draw up the mouth on the left side, and also an inclination to turn the head and body to the left. When his attention was directed to bright objects he would apparently try to look at them, but his eyes usually turned to the left. His hearing seemed to be dull, but so far as could be determined the cutaneous sensibility was unimpaired. No changes were found by ophthalmoscopic examination.

Dr. Charles K. Mills, who referred the patient to me, placed the child under observation in order to detect, if possible, the

[1] Read before the Philadelphia County Medical Society, November 25th, 1891.

[2] "The Field and Limitation of the Operative Surgery of the Huma Brain," *Annals of Surgery*, July and August, 1885.

exact character of the spasms. He was watched carefully in several seizures. Usually he squealed at the beginning of the paroxysm and his face had a vacant look. The spasm began with a lifting movement of the entire body, as if with the muscles of the trunk, much like a sudden effort to rise from a recumbent to a sitting position. About the same time, as nearly as could be judged, the eyes and head turned to the left. The eyes did not keep to the left but oscillated with the jerking movements of the body; the head, however, continually turned to the left. The left leg and arm were spastic in slight flexion and were lifted up and projected outward and forward, the limbs on the right side were flaccid, but were projected forward and upward with the jerking movements apparently communicated from the trunk and the left limbs.

Another description of the attacks records that the child awakened suddenly from sleep with a toss of the body, as if badly frightened, with the head and eyes at once turning to the left. The left arm was extended forward and upward stiff and rigid, with the thumb and little finger pointing backward, the other fingers being slightly flexed. Both legs were also tossed upward in the air, the left more projected than the right. His body was lifted up and down during the attacks.

It was difficult to determine any signal symptom or serial order of movements. The spasm was both tonic and clonic, and certainly most marked in the limbs and face of the left side. The movements of the leg and arm were those of projection and protraction, and were rather movements from the shoulder and hip than from and in the distal portions of the limbs. The movements of the head, trunk, face, and limbs were often nearly coincident, but the conjugation of the head and eyes seemed certainly to be most commonly the initial movement.

The above description is taken from a former report of the case.[1]

Dr. Mills thought that the symptoms seemed to point to lesion of the area for conjugate deviation of the head and eyes, and certain associated movements of the trunk, thigh and arm. It was, therefore, determined to trephine over the posterior portions of the first and second frontal convolutions.

After encircling the head with a rubber bandage to prevent hæmorrhage from the scalp, I made an opening with an inch and a half trephine placed one and a quarter inches in front of the fissure of Rolando and a little to the right of the median line. Behind and below the opening so made I cut out another button of bone with a one and a quarter inch trephine. The spurs of bone between the two holes were cut away with forceps. One point of the aura was abnormal in thickness and rather more adherent than normal. This condition did not seem to be caused by a Pacchionian body.

A flap of the dura was raised. The pia mater was very œdematous so that it could be pitted with the finger. A thin, yellowish-white membrane was found lying loosely upon the pia-arachnoid and had probably separated from the dura when the flap of that membrane was raised. This abnormal membrane was removed. Small electrodes applied to the convolutions failed to induce conitaction of the left arm. This electrical test was repeated but failed to give results, though no antiseptic solution had come in contact with the brain tissue before the electrodes were used. Incisions in the pia allowed the serum, which caused the œdema, to escape. When the convolutions were thus clearly exposed there was no evidence of change in their structure or of any subjacent lesion. The dural flap was then sutured in position, and the portions of bone, which had been kept in antiseptic solution at a temperature of 105°, were replaced. Some catgut threads were laid beneath the buttons of bone and carried through the incision in the scalp to give drainage.

The child was under my observation for nineteen days, during which time there were only three epileptiform attacks and these were within two or three days after the operation. They were all slight and would scarcely have been recognized as pathological symptoms if the previous severe attacks had not formed part of the clinical history. A large amount of cerebro-spinal fluid escaped for several days through the opening left by the catgut drain, which was removed a day or two after the operation, and also through a small hole in the line of incision which had not healed by first intention as had the rest of the wound.

Bromide of potassium, calomel, and small amounts of alcoholic stimulants were given to the child during the after-treatment.

When he was discharged from under my immediate care his general condition was good, temperature normal, and there had been no escape of cerebro-spinal fluid for three days. The two small openings in the scalp were covered with small crusts.

[1] *Polyclinic*, April, 1889, p. 299.

Two weeks later the child died, but the history of the intervening period is unknown. I heard only indirectly of his death. No post-mortem examination was made, but indefinite information has come to my knowledge, which leads me to believe that suppuration under the scalp occurred.

This case is one of a class in which there is a great temptation to operate in hope of finding some removable lesion of the cortical centres. The findings are usually negative; and the results only temporarily satisfactory, even when the patient entirely recovers from the lesions incident to the operation. Unless the localizing symptoms and signs are more definite than in this instance, I think that in similar cases I shall hereafter be almost inclined to avoid operative interference. This provisional conclusion has been reached by a consideration of cases in the treatment of which I have been concerned, or with whose results I am familiar.

Case II.—*Traumatic epilepsy resulting from unsuspected fracture; trephining with discovery of an irregular projection of bone on the interior of the cranium.*—A man, J. H., aged thirty-four years, while working as a puddler, about eight years ago, received an injury on the left side of the head by being caught between an iron lever of a furnace door and a brick wall. He was not treated by a physician, and only lost about two days from his work, although the injured region was poulticed by him, and was the seat of a discharge for four or five months. No portion of bone came from the wound, and there were no special symptoms.

Several years ago he had venereal sores upon the penis, but no suppurating inguinal glands or syphilitic developments. Chills and fever, several years ago, constituted the only illness from which he suffered.

An examination of his head, after shaving, revealed several insignificant scars, and just above the zygoma on the left side, a half inch in front of the auricle, a depressed cicatrix sufficiently deep to hold the tip of the little finger. This was the scar left by the injury received eight or nine years ago. The cicatrix involved the temporal muscle, as was seen by the dragging of the skin over the scar during mastication. There was no evidence of depression of the skull in any other part of the cranium, and this depression did not seem to involve the underlying bone. His intelligence was good; but the patient said that he did not remember as well as he could a few years ago, and that at times his eyesight was not good. He shows at times a little mental deterioration. An ophthalmoscopic examination of the eyes gave negative results.

The patient states that about two and a half years ago he had an epileptic fit after working in a hay-field on a hot day, and that since that time he has had marked seizures about every six weeks, with lesser attacks more frequently. He has but one epileptic fit at a time, from which he rapidly recovers, and is soon able to walk about. After such attacks he feels weak for some time. For several years he has had severe headache, not confined to any one portion of the head, and just before the epileptic seizure he feels a jerking sensation on the right side of the nose. He complains that his general health has deteriorated, but there is no apparent loss of flesh.

On the 26th of September of the present year (1891), I turned up a large flap of the scalp and found, after cutting through the temporal muscle, a depression in the skull one inch in length and three-eighths of an inch in width. This fracture was a surprise to me because of the history of the case and the situation of the injury over the thick belly of the temporal muscle. A three-quarter inch aseptic trephine was applied above and behind the depression. This cut through the bone with some difficulty, because the upper portion of the disc was much thicker than the lower part. Unfortunately my segment trephine had been forgotten, or this part of the operation could have been more expeditiously performed. Thinking I had cut entirely through the skull, I endeavored to pry out the disc, but removed simply the outer table of the button; I found that between it and the internal surface there was a portion of fibrous tissue entangled. It was probably this portion of tissue entangled in the bony cicatrix as a result of the fracture at the time of the injury that enabled me to lift out so readily the upper surface of the bony disc. The entangled tissue was doubtless pericranium. Removal of the interior table of the disc revealed below and in front of the opening a teat-like elevation projecting from the lower surface of the skull and pressing upon the dura. This elevation was about one-fourth of an inch higher than the general surface of the interior table, and was the apex of an irregular elevation due to consolidation of a number of comminuted fragments of the inner table. The irregular lines of fracture, with the fragments displaced in varying de-

grees, are shown on the button removed and the rest of the bone subsequently cut out with gnawing forceps.

The specimen shows this condition very satisfactorily, though somewhat mutilated by the gnawing forceps with which the adjacent bone was removed after the original button was taken out. The depth of the skull wound and the thickness of the temporal muscle made it rather difficult to operate neatly, and my desire to get rid of the portion of bone pressing upon the dura, without prolonging the operation or increasing its severity, caused me to sacrifice the specimen in the interest of the patient. The dura was not opened, threads of catgut were use for drainage and a dry sublimate dressing was applied.

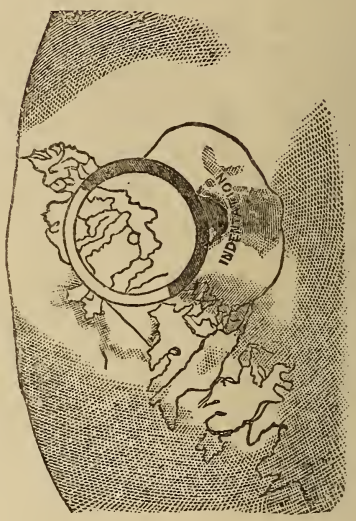
The following day the wound was found to be healing by first intention, and the drainage threads were removed. Bromide of potassium and chloral were given for two nights, and then twenty grains of bromide of potassium three times a day were ordered as a continuous treatment.

On the third day after the operation the patient had a sensation of twitching at the side of the nose similar to that which formerly preceded the epileptic seizures; but he had no fit. The wound healed by first intention, the temperature never rose above 98.6°, and on the eleventh day after the operation the patient was sent to his home in the centre of the State. He felt exceedingly well after the operation and expressed his satisfaction at the improvement of his condition. I suggested that the bromide treatment be continued by his physician, Dr. J. P. McCleery, under the idea that removal of the surgical cause of epilepsy should be looked upon as only a part of the treatment. I believe that in all such cases internal treatment should be combined with surgical procedures, and that the epileptic habit should be controlled by a prolonged course of bromides after the mechanical cause has been removed.

Seven and a half weeks after operation his physician reported that he had suffered no return of his epilepsy and was about to return to work. As far as it goes this statement is gratifying, but much more time must elapse before we can feel sure of a cure having been effected. The lesion is certainly one of those in which trephining ought to be eminently beneficial. Punctured fracture such as this should always be subjected to immediate trephining at the time of injury.

The following cuts (Figs. 1 and 2) represent the external and internal appearances of the skull in a case trephined by me some years ago. There was a small scalp wound through which I could with my finger-tip feel what I thought was rough bone. I found by incision that the roughness was due to an unusually irregular lambdoidal suture with Wormian bones; and that the only bony lesion caused by the blow received from

Fig. 1.

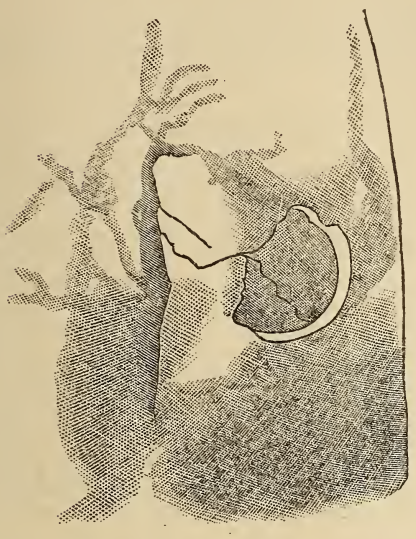


Outer surface of fractured cranium showing lambdoidal suture, point where trephine was applied, and small indentation looking like entrance of a vein made by the blow.

the pitcher, with which the patient was struck, was a small dent, looking like the opening for the entrance of a vein. The character of the vulnerating force, however, induced me to trephine. The removal of the trephine button and the insertion of a probe between the dura and the cranium discovered nothing except a small fissure on the inner surface of the disc. Death occurred within a short time from alcoholic delirium; and the autopsy revealed a T-shaped fracture of the inner table with a shelf-like detachment of quite an area of bone. If this patient had lived he would probably have had secondary epilepsy, as occurred in the case just reported. The urgent necessity of primary trephining in such punctured fractures, even when no symptoms are present, is fully illustrated by these cases. The many deaths from cerebral abscess and other inflammatory processes, following the receipt of punctured fracture

of the cranium, long ago justified the surgical conclusions that trephining in such injuries should not be delayed until the advent of symptoms of encephalic inflammation. The epilepsies resulting in cases which have

FIG. 2.



Inner surface of fractured cranium, showing cut made by trephine and large area of inner table driven inward under the small external indentation. The trephine has not cut entirely through the bone where the inner table is driven inward.

escaped the immediate dangers of encephalitis add another argument to the wisdom of immediate operation in punctured fractures.

CASE III.—*Secondary trephining for traumatic epilepsy; death from aseptic cerebral inflammation.*—In June, 1891, I operated upon a man, J. T., aged twenty-eight, with the following history:

While working in a mine he had been struck upon the head with a huge mass of coal and rendered senseless. The attending physician, Dr. James D. Harvey, found a fracture of the skull, and upon the day of the injury removed a portion of the bone. According to the patient's statement he recognized no one for fourteen days, and was, therefore, probably unconscious during that time.

After consciousness returned his left arm was paralyzed, but gradually regained power. Eight months afterward he had an epileptic seizure, and has had epileptic paroxysms at irregular intervals ever since. He is aware of the approach of a convulsion by nausea, dizziness and disorder of vision. Occasionally he has time, after the premonitory symptoms, to sit down before the fit occurs. He thinks that he ordinarily falls in the convulsion, but he does not bite his tongue at such times, though he froths at the mouth and grinds his teeth. The attacks have occurred as often as one or two in a day, but he has gone as long as four months without a paroxysm. The ophthalmoscopic examination reveals a normal fundus, clear media, and hyperopic refraction. He is unable to say in what part of the body the muscular spasm begins.

A large triangular depression is seen upon the right side of the head, the upper margin or base of which is one and three quarter inches to the right of the median line and almost parallel to it. The apex of the triangle points downward and forward toward the ear. The anterior margin of the depression is near or a little behind the fissure of Rolando, and the centre of the depression is over the superior parietal convolution, or in that vicinity. The deepest portion of the depression is that near the middle line of the skull, at which part its depth is fully a half inch · the edge of the depression at this point is almost vertical. The interior and posterior borders are less abrupt. The angle, which I have called the apex of the depressed triangle, is about two inches above the ear, and a little behind a vertical line drawn upward from the ear. The margins of the depressed area form an equilateral triangle, each side of which is about one and one-quarter inches in length. There are a number of other scars on the head, one or two of which radiate from this depression. There is distinct weakness of the grasp of the left hand, but no marked difference in size of the hand or the arm. The patient complains of the left hand feeling differently from the right. There is no muscular contracture and no apparent change in the electrical reaction or in mensuration.

On account of the epileptic attacks in this case I determined to operate and remove any apparent cause of irritation. If nothing abnormal was found, I intended to remove the cicatrical tissue in the bony gap and also the bony margin of the opening in the skull. Accordingly I made an elliptical flap in the scalp which disclosed a triangular depression in the skull corresponding with the indentation seen externally. This was filled in with fibrous tissue, which I dissected out of the bottom of the depression. The bone was so thick that the gnawing forceps

could not cut away the edges, hence, I used an aseptic trephine and removed a disc one inch in diameter from one corner. Subsequently I made four small holes along the edge of the depression with a half-inch trephine and then was able to gnaw away the edges with gnawing forceps. The soft tissues were yellow, and pigmented in places with particles of carbon, evidently due to coal dust ground into the wound at the time of the accident.

Before the operation pressure upon the scalp gave the sensation of a small cavity filled with air under the integument. It resembled the sensation experienced when a varicose vein is palpated. Removal of the skin over the gap in the cranium did not alter this tactile phenomenon. The yellow pigmented tissue, found as above mentioned, was not brain tissue; and when cut through disclosed what looked like the interior of an emptied cyst, because the inner surface of the tissue had a smooth, glistening surface. No fluid escaped or had escaped by puncture. After having dissected away a considerable portion of this material, and having removed the edges of bone along the entire circumference of the bony opening I reached normal brain-tissue. Hæmorrhage from the cerebral wound and from the periosteum was profuse. It seemed impossible to stop that which came from the brain and its membranes, which were fused together in an almost indistinguishable mass at the bottom of the deep hole. The triangular opening in the skull measured about two inches along each margin. The pulse became very feeble, counting 165 a minute. Prolongation of etherization and operation seemed unwise.

After unsuccessful attempts to stop the bleeding by ordinary methods, I concluded to grasp all the bleeding points with hæmostatic forceps which should be left in the wound. This was done, and five forceps left in the wound with their handles protruding. Iodoform powder was dusted upon the surface of the exposed brain and strips of iodoform gauze packed into the cavity. A few sutures were applied after the flap had been replaced; the gauze strips and hemostatic forceps projected from one corner of the wound. A voluminous dressing of iodoform gauze and cotton was then applied and the patient put to bed. Seven and one-half hours after the operation the dressings were saturated with bloody serum, and, therefore, in order to avoid sepsis, I determined to reapply them and to remove the hemostatic forceps at the same time. This was done carefully, the gauze withdrawn, and the wound redressed with a dry antiseptic dressing. In drawing out the strips of gauze a little oozing of blood occurred, but this hæmorrhage I did not think of sufficient importance to prevent my closing the whole wound with sutures and without drainage.

The next morning the patient showed great restlessness, but was in a condition of hebetude. He, however, made his wishes known when he desired to urinate. Bromide and chloral were given to control the restlessness.

On the second day respiration varied from 25 to 40 in a minute, and the temperature was 101°. During the day the patient's condition was fairly good, though he was difficult to control on account of his restlessness and irritation. The urine was passed unconsciously. A turpentine enema was given; bromide and chloral were continued. On the third day after the operation it was necessary to give the patient one-sixth of a grain of morphine hypodermatically, and to strap him in bed because of his tossing from side to side. During the day he became hoarse, and I discovered at the base of the right lung harsh râles, probably bronchitic. The temperature was now 101.6°, while his respiration was between 35 and 40.

On the fourth day after the operation the note is made that he slept after a hypodermic of morphine, one-sixth of a grain, and is quieter. Respiration 40 to 45. His breathing, however, was embarrassed and harsh, somewhat of the Cheyne-Stoke's type. At 7 P.M. respiration was 50; temperature 102°. The wound had been left undisturbed since the evening of the operation when the hemostatic forceps were removed. The rise in temperature and the patient's restlessness made me fear that there had been something amiss in my antiseptic precautions. I, therefore, determined to inspect the wound. Upon removing the dressing, I found the flap bulging and detected a feeling of fluctuation when my finger was put upon it. I expected to find pus under the flap, although the wound had healed by first intention. I tore open the union, but no evidence of pus existed; a soft aseptic clot of blood, however, lay under the flap. I removed the clot and explored the cranial cavity through the operation wound with my finger in search for pus. The cerebral tissue was disintegrated and soft, but no purulent collection was found. I moved my finger in various directions in the pultaceous mass, and finally, when my little finger was buried its entire length, came upon a hard mass at the

bottom. This, I presume, was one of the great ganglia. The tissue overlying this part was almost fluid. There was no odor of decomposition nor evidence of pus. At the time of this exploration the patient was moribund, and I felt fully justified in these radical measures. Unless I found pus he was sure to die.

The dressings were reapplied; hypodermatic injections of strychinne were given. Respiration gradually failed and the patient died the next morning, which was the fifth day after the operation.

It seems hardly possible that the fatal symptoms were due to pressure from such a small amount of hæmorrhage under the flap, since there was much space by reason of so much bone having been cut away; and, morever, the blood, if causing tension, would probably have readily escaped before the wound had united. I concluded, therefore, that death occurred from aseptic cerebral inflammation leading to disintegration and softening of the brain tissue. The pulmonary symptoms may have been secondary; or he may have had a congestion, preliminary to an acute pneumonia, acting as a prominent feature in the fatal result. Rapid respiration was certainly an early symptom.

The case is to me exceedingly instructive, because the indications for operation were clear, and because death occurred notwithstanding what seemed to be perfect aseptic conditions of the wound, during its entire course. It is a good illustration of the fact that modern surgery has not rendered serious operations entirely devoid of dangers. The diminution of the death-rate in operations has been great in recent years, but certainty of recovery is by no means as absolute as some reporters of operations would have us believe.

The next case is reported because of the youth of the patient.

Case IV.—*Trephining for depressed fracture of the skull in an infant seven months of age; recovery.*—A mother, while carrying her seven months' old child along a railroad track, fainted or had epileptic seizure, and fell, dropping the child. When she regained consciousness the baby was whining and fretting a little, but did not seem badly hurt. After the mother reached home and removed the child's wraps she discovered a large indentation of the skull on the right side of the head, which she supposed was due to the child's head having struck against a railroad tie, or upon the iron track. The baby did not have any symptoms of brain implication.

When seen by me on the next morning the infant was perfectly comfortable, had slept well all night, played as usual, and had a good appetite. The mother believed the depression to be less marked than when the accident occurred. Examination revealed an irregular depression in the parietal and occipital region on the left side of the head. The lower extremity of the vertical diameter of this depression was about two centimetres above and five centimetres back of the top of the ear. The depression extended upward six centimetres. The horizontal diameter—that is, that parallel to the sagittal suture—began at a point near the anterior portion of the posterior half of the parietal bone, and extended backward six centimetres, very nearly bisecting the vertical diameter. The depression at its deepest portion was fully a centimetre below the surface of the skull.

At this time the patient's temperature was normal; pulse 120. During the night two grains of sodium bromide were given because of slight restlessness. The bowels were opened by a soap suppository.

On the second day after the accident I found the child feeling well and the depression less marked than on the previous day, when I made the first examination. I felt unwilling, however, to let the injury go without surgical treatment and therefore determined to make at least an exploratory incision, because the injury had been so severe as to make a very deep depression. The possibility of secondary symptoms, such as epilepsy or impaired intellect, seem to me to indicate this slight operative interference.

An Esmarch's bandage was carried around the head before the incision was made to prevent bleeding. A horseshoe flap was then dissected up at the point of injury. The bone was markedly depressed, showing a condition similar to green-stick fracture. I thought I could cut through the cranium with a strong knife but found it necessary to use a trephine. A small trephine opening was made through very thin bone at the anterior edge of the depression and the portion pushed down upon the brain easily elevated with the end of a grooved director. A few bleeding arteries were twisted, and the edge of the scalp wound drawn together by catgut sutures. Boric acid powder and dry sublimate dressing was applied.

The patient reacted from ether promptly and went quickly to sleep. Two grain doses of sodium bromide were given at intervals until ten grains had been taken. The patient was restless through the night, but a few

drops of paregoric quieted. The bowels were kept open by injections of oil.

The temperature the day after the operation reached 101.8°, but soon all symptoms of fever disappeared, and on the seventh day the dressings were removed. The wound was found to have healed by first intention without suppuration.

At the end of the sixteenth day the patient was sent to his home in New Jersey entirely recovered.

In this case the accentuated character of the depression was the factor which led me to adopt operative procedures, although I know the tendency for depression of the skull in healthy infants to correct itself spontaneously.

About eighteen months ago I saw a child who had received during birth a very marked indentation of the skull because the head had become locked on the promontory of the sacrum during delivery. The depression was situated on the left side of the head, and included portions of the frontal and parietal bones near the anterior fontanelle. It was about two and a half inches long and quite deep. The case was one of difficult labor requiring forceps at the hands of Dr. Anna M. Fullerton, and the child, when born, was in the first degree of asphyxia, requiring the warm bath and artificial respiration. The child had frequent convulsions, beginning twenty-four hours after birth, evidently due to implication of the brain; yet I declined to operate because I thought that the indentation was probably not associated with actual fracture of the soft bone. The convulsions ceased within twenty-four hours, and although the patient was under observation for several weeks, I never could convince myself that operative procedures were justifiable. The depression gradually lessened and when the child was last examined by me seemed unimportant. The medicinal treatment of the child consisted of sodium bromide and potassium iodide. I have sometimes felt in regard to this case that the subsequent history might perhaps show that it would have been better to have interfered. I have not been able thus far to succeed in tracing the subsequent history of the little patient.

Case V.—*Specimen of cerebral tumor which could have been readily removed by surgical means.*—The brain herewith presented shows a tumor occupying the parietal region and was obtained from a subject in the dissecting-room of the Woman's Medical College of Pennsylvania. The history of the case, is therefore, exceedingly indefinite, though through the courtesy of Dr. George S. Robinson I have been able to obtain the following notes:

The patient was a woman, aged 35 years, of intemperate habits, who had, so far as known, no injury of the head and was not discovered to be syphilitic. She was an inmate of a public institution and was sent to its infirmary about a week before her death, complaining of pain in the head which seemed to be somewhat relieved by pills of an anti-neuralgic character. The headaches continued, however, notwithstanding medication, and for about two days vomiting occurred. The patient then became comatose and paralysis of the right arm and leg supervened. The pupils were somewhat dilated and did not respond to light. Respiration was slow and the face flushed. No convulsions occurred, but there were slight twitching of the facial muscles. The patient was not noticed to be blind or deaf. Death took place on the sixth day after admission to the infirmary.

An examination of the specimen (Figs. 3 and 4) shows a flat, circular tumor in the right parietal region lying between the dura mater and the cerebral hemisphere. The convolutions are pushed downward but are not infiltrated in the least degree. The dura has not been preserved, but it is quite evident that the growth was attached to the inner surface of the dura, since its upper surface is torn and it has no attachments to the convolutions, but can be lifted out of its bed without disturbing their integrity. The tumor is almost circular when inspected from above, being 6 centimeters in the antero-posterior diameter, and 6.5 centimetres in the transverse diameter. It is flat from above downward, varying from 2 to 3 centimetres in thickness. It occupies the right parietal region upon the superior aspect of the cerebrum. Its anterior margin lies in a line with the calloso-marginal fissure, and pushes forward the ascending parietal, or posterior central, convolution. The tumor extends backward to the parieto-occipital fissure crowding downward and backward the first occipital convolution. It extends outward and downward to the posterior end of the parallel fissure, or the first temporo-sphenoidal fissure, pressing upon the angular gyrus. The first and second parietal convolutions are flattened and lie underneath the tumor in the concavity made by its growth and producing pressure downward. On the inner aspect of the hemisphere the tumor presses the convolution downward, being nearly 2 centimetres thick where it lay in contact with the falx. The anterior

edge of the tumor is about 1 centimetre further forward than the posterior edge of the corpus callosum. The gyrus fornicatus and the precuneus are pressed downward, but the cuneus does not appear to be pressed upon or displaced.

FIG. 3.

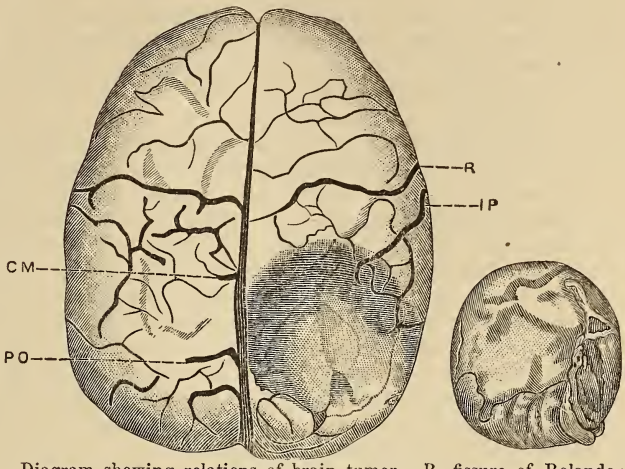


Diagram showing relations of brain tumor. R, fissure of Rolando; I P, inter-parietal fissure; P O, parieto-occipital fissure; C M, calloso-marginal fissure. The tumor has been lifted out of its bed.

moval. Its location immediately under the dura, its freedom from attachment to the cerebral convolutions and its moderate size would have made its removal easy. Its location behind the motor area is probably the reason that the patient's symptoms were not marked until just before the fatal termination of the disease. Her habits of life and surroundings were such that she would

FIG. 4.

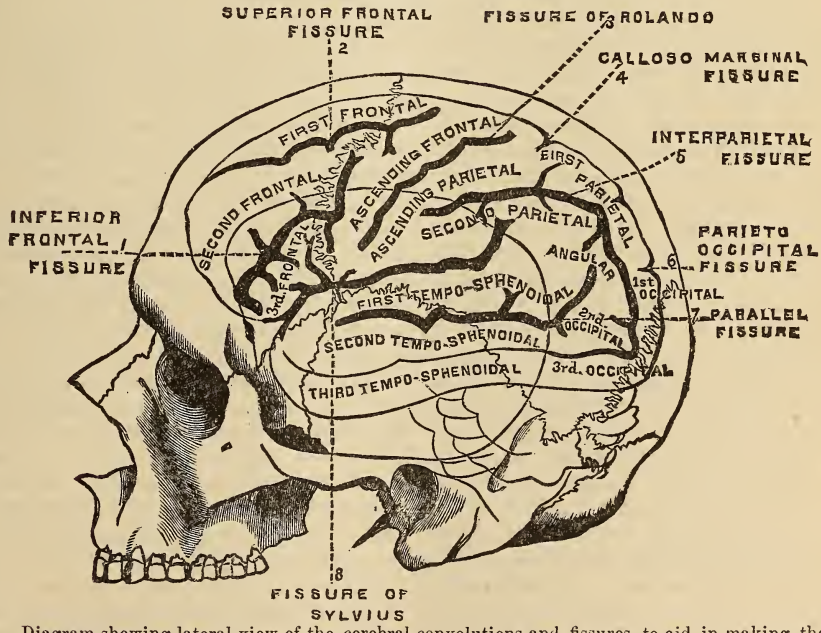

Diagram showing lateral view of the cerebral convolutions and fissures, to aid in making the description clear.

No surgeon can look upon this specimen without a feeling of regret that he could not have had an opportunity to attempt its re-

not be likely to call a physician's close attention to the early manifestations of cerebral disorder, if indeed these were apparent to the patient herself. A large opening made with trephine, gouge, or saw, followed by a similar incision of the dura would have enabled the operator to lift the tumor from its bed without hæmorrhage or disturbance of the cerebral convolutions. The growth is probably a fibroma.

The occurrence of right-sided paralysis seems rather curious, but Dr. Robinson states that he is sure of the correctness of this note, for he remembers that she used her left hand during her final illness. There is no evidence of a second tumor on the left side. Possibly the growth may have so pressed against the falx as to have impeded the current in the superior longitudinal sinus, and thus have given rise to pressure on the left cortical centres near the upper end of the fissure of Rolando. Unfortunately, I did not see the specimen until after the dura and falx had been removed.

Case VI.—*Probable basal cerebral tumor, in which operation was deemed inadvisable.* —In September, 1889, a man, aged thirty-four, was referred to me by Dr. H. C. Bloom, who had reached the conclusion that his patient was probably suffering with brain tumor. The history was somewhat difficult to obtain from the patient, who had evidently some impairment of mental faculties. In childhood he had had otorrhœa in each side, and thought that his present ailments, of two or three years' duration, had succeeded a renewed discharge from the left ear. About a year before I saw him he had fallen insensible; but for a year and a half previously he had had attacks of severe pains in the head, to the left of the median line. Some failure of vision had been observed for eighteen months; occasionally he walks unsteadily, but there is no apparent loss of power in arms or legs. His family thought his mental traits had shown change for several years. He is now becoming fat, sleeps a good deal, and is somewhat "weakminded" in his conversation and facial expression. There was no direct history of syphilis. Optic atrophy was found in both eyes; being more marked in the left, with which he could only see enough to count figures. The vision of the left eye was $\frac{4}{LX}$. Examination showed him to have lateral hymonymous hemianopsia and Wernicke's pupillary reaction. The fields of vision indicated a left-sided lesion. No deviation of the eyes was determined, but he thinks he has at times had double vision. Both tympanic membranes were perforated. He had had no epileptic seizures, but, as above stated, had once fallen unconscious. The urine had a specific gravity of 1010 and contained neither albumin nor sugar. The grasp of the right hand was stronger than the left, accountable perhaps to his profession—that of a dentist. Thermometric examination for several days showed him to be free from fever.

No anæsthesia nor paresis could be determined. Dr. B. Alexander Randall's examination resulted in finding in the left ear an old cicatricial condition, with a mere trace of discharge. The original trouble had probably been present in childhood, and was now in abeyance; though occasional exacerbations had in all probability occurred. The right ear was in a state of chronic suppuration of the attic and adjacent cavities, with some likelihood of the existence of diseased bone. No involvement of receptive or central auditory apparatus was discovered by the use of tuning forks. The patient's symptoms were thoroughly studied for me by Drs. Charles K. Mills, H. C. Wood, Edward Jackson, B. A. Randall, A. W. MacCoy.

From Dr. William Osler, who had seen the man some months before, I learned that then he had had an intense optic neuritis, but at that time no hemianopsia. Dr. Osler suspected a slowly growing neoplasm; probably located in an anterior location, because of the early alteration in habits.

Dr. Mills was inclined to think that the symptoms shown when the patient came under my care pointed to a lesion between the optic chiasm and the primary optic centres. This he considered might be a tumor or abscess of the inner part of the temporal lobe, encroaching on the optic tract back of the chiasm or a similar lesion of the cerebellum advancing and invading the more anterior structures.

Dr. Wood believed the localizing symptoms pointed to a lesion encroaching upon the corpora quadrigemina or optic chiasm, which was most probably either a localized meningeal inflammation with much exudation, due to diseased bone at the base of the skull, or a tumor there situated. He thought it possible that an abscess might exist in the temporal or frontal lobe, but there was little evidence to indicate this being a probability.

This case was one that offered a good many points of surgical interest; but after determining that the lesion was probably basal and on the left side, I declined to operate, because there was no evidence of

the left ear being a probable cause of intracranial suppuration. If the symptoms had pointed to a right-sided lesion, the condition of the right ear would have influenced me strongly toward operative measures, looking to the evacuation of a temporal abscess. The association of chronic aural suppuration with cerebral abscess is so well known that I think I should have strongly inclined to exploratory trephining.

I accordingly declined to operate, and sent the patient home. I heard from him frequently, but he gradually lost vision and mental power. I had arranged for, and obtained permission for an autopsy; but when he died the past summer no word was sent me. Previously to death he had violent pain in the head, a prolonged chill, several successive convulsions and coma with high temperature. These symptoms occurred suddenly and terminated fatally in four days. Before that time he thought his eyesight, which had been almost totally lost, was improving. The time he survived after my examination, nearly two years, leads me to believe that our abstinence from operation was correct; since the lesion was more probably a tumor than an abscess. If a tumor, its removal was certainly impossible.

This case presents a picture different from the specimen before you, in which the tumor could have been lifted out so readily. I show a diagram of the cerebral convolutions which may aid in following the description of these two cases of cerebral tumor.

I fully recognize that the record of these few cases has not been one of brilliant results. The death of some of the patients, and the short time between operation and this report in others, make the communication in some respects unsatisfactory. It has seemed to me, however, that there are elements of interest in the histories which will afford food for thought and open the way to discussion. It is for these reasons that I have been tempted to give these clinical histories which are certainly not in any way remarkable.—For discussion, see Society Reports.

DETAILS ABOUT COLORADO SPRINGS IN THE CLIMATIC TREATMENT OF PHTHISIS.

BY J. P. CROZER GRIFFITH, M. D.,
CLINICAL PROFESSOR OF DISEASES OF CHILDREN, UNIVERSITY OF PENNSYLVANIA.

In spite of the numerous so-called "cures" for phthisis which have been recommended during the last few years, the only established fact of value which stands fast is that there are certain localities where the disease rarely or never occurs, and that very many patients, sent from elsewhere to some of these places, may recover entirely from it. In the light of this fact the choice of situations for our consumptive patients is a matter of the utmost importance, as upon it may depend the issue of the case.

In a former paper[1] I endeavored to lay stress upon the existence of a *climatic idiosyncrasy*, or, as it has also been called[2], "individual adaptability"; viz., that often for no apparent reason a climate which suits one individual may in no way suit another. Although we may sometimes base upon the general characteristics of a patient an opinion as to what sort of climate will probably prove most suitable, we are oftener but little able to determine this in advance, and are obliged to make our decision in accordance with the results which have been obtained by general experience in the largest number of years.

Nearly all statistics go to show that the results in the climatic treatment of phthisis are much better at high altitudes than at low. The truth of this is evident in the following tables, constructed from the carefully compiled statistics of Dr. S. E. Solly[3], which are based upon all the published statistical results obtainable and suitable for the purpose of analysis. (In Tables I, II, and III.)

It is to be noted in these tables that the "benefited" includes both patients who have improved and those actually cured.

Comparing now the condensed results in a third table, we have an excellent illustration drawn from the comparison of a large number of cases, of the therapeutic value of high altitudes in phthisis as compared with low.

With the knowledge of these statistics we may be in a position to recommend a high altitude to our patients, but beyond this it is sometimes very difficult to pass. We must be guided here largely by such features as convenience, comfort of living, pleasurable society and occupation, and the like, which are by no means unimportant factors in determining the amount of benefit to be obtained.

In reading somewhat extensively the literature of the climatic treatment of phthisis,

I have been impressed by the absence of exact information concerning these details of the various health resorts, at least in many of the books and articles consulted.

Having but recently returned from spending several months in Colorado Springs, and having endeavored by observation and interrogation to learn some of the facts regarding it, I am led to offer the following informal remarks in the hope that they may prove of some use to colleagues about to send patients to the west.

From the point of view of *climate* alone there is probably little to choose between various parts of Colorado and the surrounding country. It is much alike in all, and, except that the soil of some places is more clayey, and therefore not to be preferred, one locality can hardly be selected above another. As regards, however, actual comfort in living, Colorado Springs presents certain decided points of advantage. It was founded about twenty years ago as a health resort, and has remained typically such. It is situated on a table-land 6000 feet above the sea and about six miles to the east of the foot of Pike's Peak. It is seventy-five miles south of Denver and forty miles north of Pueblo, on the main line of the Denver and Rio Grande railroad. The outlying range of the Rocky Mountains, of which Pike's and certain other peaks are members, is in full view, while in the other direction, to the east, is an uninterrupted view of the plains—a peculiar and beautiful combination rarely seen.

The houses are for the most part far apart, and each, even the small ones, surrounded by its own plot of ground. There are several handsome business blocks, but the town does not do much business in proportion to its population. Large numbers of trees, chiefly the rapidly growing and leafy cotton-wood, are planted along the streets, making them very shady in summer. Indeed, seen from the top of Pike's Peak, Colorado Springs looks like a small patch of forest.

The trees, however, are no indication of dampness, for, planted as they are in a soil which is almost purely gravel, they would promptly die were it not for persistent and watchful irrigation. The same is true of the really beautiful summer grass. Nothing but the greatest care coaxes the verdure out of plains which would otherwise be arid.

Colorado Springs is provided with a system of rapidly moving trolley cars, which not only carry passengers to different parts of the city, but extend as well to Manitou and other situations in the surrounding country.

There are numerous good drives, leading both towards the mountains and the plains. The celebrated Garden of the Gods is a drive of but four miles from the town.

The gravelly soil, already alluded to, is so dry that one cannot but be struck by the curious disappearance of the snows in winter. Walking about one can kick this up and find only dust underneath. In fact the snow seems not to melt but to evaporate. Only when exceptionally heavy does it produce mud, and this lasts only for a short time—a day or less.

The evaporation of the snow and the rapid disappearance of any mud is of course in great measure due to the extreme dryness of the air. Persons newly come to Colorado often complain of this, as it causes chapping of the lips, uncomfortable dryness in the nose and the like. I have in fact, noticed some invalids drawing in with pleasure the air of an occasional damp day. To the majority, however, the dry air is peculiarly pleasant and invigorating. Meteorological observations[1] showed a relative humidity for the vicinity of Colorado Springs for four years of only 45.8, as compared with 65.8 for Los Angelos, 69 for Jacksonville and 70.2 for New York.

Sunshine in Colorado Springs is abundant. The number of clear days estimated for five years gave an average of 194, with 128 fair and 43 cloudy days. The average yearly number of cloudy days in New York, estimated for the same time equalled 109. The amount of rain-fall is, as a rule, very small. The average yearly fall estimated for ten years was 15.87 inches, as compared with 42.7 inches in New York.

As in all places of high altitude the direct rays of the sun are powerful. In summer the days are often hot, but rarely so oppressive as in regions where the air is moist. In winter, on the other hand, the warm sun's rays enable patients to sit in the open air a large portion of each day.

Other characteristics of high altitude seen in Colorado Springs are the sudden and violent winds and the rapid alterations of temperature. These are, of course, distinct disadvantages, so far as *comfort* is concerned. Unfortunately an equable climate, with gentle zephyrs and the like, is only to be found at low altitudes, and usually in the warm moist regions so unsuitable for consumptives.

[1] S. E. Solly. Invalid's Day in Colorado Springs. Transac. Amer. Climat. Assoc. 1887.

With the wind and the gravelly soil one encounters at times dust storms which are extremely disagreeable. As to their hygienic effect I cannot do bettter than quote the words of a phthisical but convalescent lady whom I had the pleasure of meeting. "It seems strange," said she, "that it should be beneficial to swallow dust by the tablespoonful, but it appears to do no harm."

I should however give an erroneous impression did I imply that violent winds and dust storms were an every day occurrence.

The prevailing wind during the night and early morning is north or northwest, which commonly shifts in the afternoon to south or south-east.

Any further details regarding the weather of Colorado Springs can perhaps best be treated under a brief review of the different seasons. During the summer months, especially rare in July and August, thunder showers of short duration are exceedingly liable to occur in the afternoon; the bulk of the annual rain-fall taking place at this season. The mornings, however, are almost always clear. The nights are never damp and foggy as in late summer in the east, and I have never been able to perceive dew. The heat of the summer sun is evidenced by the thermometer rather than by the sensations, owing to the rapidity of evaporation of perspiration. At times, however, the days are as warm as in the east, but the nights are nearly always cool, and blankets are usually required on the beds.

Probably the most charming season of the year is autumn. For weeks at a time it may be that scarcely a cloud will be seen and but little rainfall. Patients can spend the entire day in the open air, and even the evenings are not injurious. The same is true of winter. Frequently the temperature in the night at this season is quite low; and now in the daytime, one realizes the difference between the sunny and the shady side of the street. The power of the sun under these circumstances can only be appreciated by those who have experienced it. The very low temperature of the northwest is uncommon, and the cold is not penetrating as is the damp cold of the east.

Spring is the least pleasant time of the year. It must be remembered, however, that seasons occasionally occur in which the amount of rain-fall and of dampness is in decided excess of the average.

In March and April there is apt to be a good deal of cloudiness with frequent snow, though, as stated already, the snow rarely produces mud. In comparison with an eastern early spring the weather is very pleasant. Occasionally during the winter and spring there prevails a peculiar hot west wind, probably coming over the mountains from the Pacific, and called the "chinook."

Turning again to some further details concerning the town and the method of life of those seeking it:—

In Colorado Springs are situated a general hospital under the charge of the Sisters of St. Francis, the State Asylum for the Deaf, Dumb and Blind, the new Printers' Home in course of construction; the Colorado College for the young of both sexes, a club and fine club-house and two sanitaria, the Bellevue and the Glockner. Both of these latter are benevolent and most deserving institutions, intended primarily for those whose means are limited. Both have been recently erected.

I have personally inspected the Bellevue. It is pleasantly situated on elevated ground, is tastefully built and furnished, and cannot but be a comfortable and cheerful home for its inmates. It is in no sense like a hospital in its internal arrangements. The patients are located in separate rooms. Those well enough to do so meet in a common parlor and dining-room. Trained nurses are in attendance, and the physicians to the institution are among the most prominent of Colorado Springs. The rates of board are $8.00 a week and upwards according to room, but even when the institution is full this hardly pays expenses. Nevertheless, cases unable to pay anything are admitted free at the discretion of the managers and physicians.

The Glockner sanitarium is conducted on the same general plan. The rates of board are $7.00 a week and upwards. A limited number of free patients are admitted. Externally it is a comfortable-looking, roomy brick building.

Colorado Springs possesses a most pleasant social life. A comparatively large proportion of the population consists of people of means and cultivation, there in the pursuit of health and engaged in no engrossing business. The society is cosmopolitan. The wants of the inhabitants are well supplied by shops of very good grade, which are confined chiefly to a portion of a single street. The markets are good. On account of the somewhat shifting population numerous houses furnished and unfurnished and of all sizes are always to be rented. The rates of rent, and indeed all expenses of living are higher than in most parts of the east. Furnished houses of six to eight rooms bring

from $35 to $60 per month, and larger ones in proportion. Unfurnished houses are of course less expensive, and it is the custom of the furniture dealers to sell their goods with the agreement that they will receive them again at about half price when the customers break up housekeeping.

My own observation leads me to believe that where whole families come to Colorado Springs for a protracted stay it is often both more comfortable and more beneficial to keep house even though in a very small way. In some parts of the town pleasant apartments of two or three rooms may be rented for housekeeping by those whose means do not warrant taking a whole house. Wages of domestics are high—from $20 to $30 a month.

The hotels or boarding houses may be patronized by those not desiring to keep house. Of the former there are several, the largest possessing 200 rooms. Rates at the hotels are from $5 a day down, with some reduction for a continuous stay. For a winter residence at a hotel it is extremely desirable to obtain a room heated by an open grate or a stove rather than by steam, as the latter is less easily controlled and provides less perfect ventilation. In fact the steam heating often makes the hotels unbearably hot in winter. Boarding houses are numerous. At the best known, table board costs $8 to $9 weekly, and a room averages $20 a month; making a total of about $12 a week. In less fashionable parts of the town good board including room may be had for $8 to $9 a week or even perhaps for less.

For those whose health permits of it, probably the most convenient plan is to choose a room to suit and to go out to a hotel or boarding house for meals. For women and for very delicate men this is frequently not feasible.

Driving and riding are the principal occupations of invalids whose strength and means permit. Horses are cheap. Well broken bronchos can be bought for from $40 to $60 and ordinary horses for a slightly higher rate. Stabling costs from $17 to $20 a month, and it is probable that even still better rates could be obtained. Livery stables are numerous and safe horses can easily be hired. The use of a horse and carriage for a half day costs only $2, and a horse and saddle $1.50 for the same time. The rates are less if taken by the month.

Comparatively few sufferers from pulmonary diseases are unpleasantly affected by the high altitude even on first arriving. But it is well to avoid much exercise at the beginning. It is a mistake to suppose that the more one exercises the better. At first simply to be out of doors, even though confined to a chair, is all that is to be recommended. The invalid should endeavor to spend several hours of each good day in the open air. Later, as strength increases and as one becomes acclimated, short walks and drives are desirable. For those in whose cases no contra-indication exists, horseback riding will be found exhilirating and healthful. It increases the vital capacity most decidedly. It is often supposed that especial virtue attaches itself to sleeping in the open air in summer. I cannot but feel that such a course is to be adopted with great caution. For those unusually robust it may be excellent, but for many it is unsuitable and merely exposes them to the risk of taking cold without offering any real advantage in lieu thereof.

I wish, too, to emphasize the great importance of wearing suitable clothing. Recent arrivals are very commonly attacked by coryza and bronchitis; attributed often to the dust, but due really to the lack of a proper appreciation of the need of watchfulness against temperature changes. In winter great coats and wraps must always be ready at hand. Woolen underwear should be worn, though this need not be thicker than is required in the east. For delicate persons with poor circulation, who tend to feel chilly at night, woolen night-wear will be found a great comfort and safe-guard, as the bed-rooms grow cold before morning. In summer women may wear wash dresses and thin underwear in the middle of the day, but should change to silk or woolen dresses for the evening; and men should not hesitate to assume light overcoats on the first evidence of chill in the air. No one should take a horseback ride of any length on summer afternoons without carrying a good rubber coat along.

It might seem hardly necessary to add that imprudences of all kinds should be carefully avoided, and yet it appears to be a common idea with many patients that coming to Colorado Springs is all that is needed to effect a cure; and invalids are often most negligent in this matter. As one writer on Colorado has pithily put it.[1] "There is no country where the invalid fool is more surely and quickly punished for his neglect of good advice." On this account

[1] S. E. Solly. Invalids suited for Treatment in Colorado Springs. Transac. Amer. Climat. Assoc. 1888.

it would be best for careless patients to be sent to one of the sanitaria referred to, as results in closed resorts are known to be much better than elsewhere, other things being equal. In fact there is hardly a question in my mind that all phthisical patients in whom the disease is in an active state are better treated in sanitaria. The very good results obtained at Görbersdorf and Falkenstein in Germany are to be accounted for largely by the constant supervision to which the patients could be subjected.

It would be well for all invalids to put themselves under the care of a local physician as soon as possible, even if they do not need treatment. Only in this way can it be determined whether they are profiting by their stay, and how long this should continue.

But a few matters remain to be considered. First of these is the question as to what phthisical patients should be sent to Colorado Springs. Of course those in the first stage of the disease offer here as everywhere by far the best chance of ultimate recovery. The earlier patients are sent the better. But even in the second stage, unless the disease is very wide-spread, permanent improvement may be looked for. Patients with cavities or with evidence of rapidly advancing disease are rarely benefited. At the same time such patients inevitably die at home, and as some remarkable cures have been effected by the treatment at high altitude I cannot but regard it as sometimes worth while to give them the chance for life, provided always that they or their friends are made to understand that but little is to be hoped for, and that a certain degree of risk attends the trial. Certain patients with very nervous dispositions are unsuited for residence at high altitudes, the great increase in the nervous excitability interfering with any good which might otherwise be obtained. Serious valvular heart lesions, especially when not well compensated, or any evidence of cardiac weakness and irritability renders the advisability of sending phthisical patients to high altitudes very questionable. Cases of phthisis florida are as doomed in Colorado Springs as elsewhere, and no possible good can be anticipated in such.

To the question in what season of the year patients should be sent one can only answer, in any. Although the spring, as stated, is less pleasant than other seasons, yet it is certainly to be preferred to the spring in the east. Patients may lose valuable time by delaying their departure for any certain season. I would strongly urge against it.

How long patients should stay can only be determined by trial in each case. A year is probably the shortest time ever necessary. For some a life-time is required. Experience seems to show that, once cured, patients have as good a chance of living at low altitudes as though the cure had not been accomplished at a high elevation. I have been unable to find any proof of the wide-spread opinion that those going to Colorado for health can, because of this act, never live again in the east. Patients who have apparently recovered and who come east and again fail in health, would probably have perished long before had they persisted in remaining at a low elevation.

I have not yet said anything of the surroundings of Colorado Springs, and at least a short notice is demanded.

Manitou, about five miles distant, is a well-known place of resort, particularly in summer. It possesses the mineral springs from which Colorado Springs is named, as there are no springs in the latter place. It is pleasantly situated close to the foot of the range of mountains of which Pike's Peak is one, the houses extending up among the foot-hills, and the place having somewhat the appearance of an Alpine village. For a summer residence it would be most pleasant, as it is a centre for tourists and is full of life and excitement. In winter, however, nearly all the hotels are closed. For those desiring to make a prolonged stay in the west; *i. e.* for invalids, I should consider Colorado Springs more agreeable.

Upon the plains and at the foot of the mountains and a couple of miles or so to the south of Colorado Springs is Broadmoor. The view of the plains at this point is superb. But few dwelling houses are as yet built, though doubtless the increasing size of the town will make building at this place and elsewhere in the suburb a certainty in the near future. Broadmoor has already become a favorite resort for the afternoons and evenings, as it possesses a handsome casino with excellent cuisine. During the past summer music has been dispensed by a small orchestra of high order. Attached to the casino are pleasant grounds and a small lake. Near by is the building of the Colorado Springs Country Club, already a favorite institution though but recently organized.

There are certain phthisical patients whose health does not flourish during hot weather. For these, and for any who find summer heat disagreeable, there are a number of situations close to Colorado Springs

which will be found pleasant during July and August. The Ute Pass, leading from Manitou northward contains several such mountain resorts of an elevation of from 7000 to 8000 feet. Among these may be mentioned Ute Park, Woodland Park, Green Mountain Falls, Cascade, and Manitou Park. At a still greater elevation is Summit Park. All of these are easy of access and much frequented by invalids from Colorado Springs. Of course there are numerous other resorts in the State, somewhat farther away, though easily reached. I spent two months at Manitou Park and found the hotel pleasant, and the situation and weather delightful. Through all this region one is practically among the pines. All of these places offer excellent facilities to those desiring to tent during summer.

None of these mountain resorts should be visited before July, and the remarks already made about the necessity of taking care in every respect apply to them with especial force. An invalid should never visit them in summer without taking warm, as well as cool clothing.

VIN. IODINII COMP. IN THE TREATMENT OF CATARRHAL AFFECTIONS OF THE AIR PASSAGES.

BY JOSEPH B. POTSDAMER, A. M., M. D.

PHILADELPHIA.

Under the name of Vin. Iodinii Comp., I have had a mixture prepared by my friend Mr. Emil Jungman, apothecary at Fourth and Noble streets, each teaspoonful containing phosphorus, gr. $\frac{1}{100}$; iodine, gr. $\frac{1}{6}$; bromine, gr. $\frac{1}{6}$; with aromatics and sherry wine. This preparation is very palatable, neither of the drugs being perceptible by the sense of taste. The dose is from thirty drops to a teaspoonful three times daily. A boy of nine can very well bear twenty drops.

The first series of cases in which the remedy was used, was those of chronic bronchitis with acute exacerbations. In all the cases, without any exception, the cough disappeared rapidly. Most of these patients had been treated on previous occasions by the usual routine treatment but the difference was so marked as to at once attract the attention of the sufferers. The expectoration in these cases immediately began to diminish in quantity and to improve in appearance. Among these cases was a man, who, during the intervals of the attacks, was perfectly free from cough but was subject to attacks of dyspepsia which was brought on by indiscretions in diet or the use of the usual remedy for his disease. The use of the vin. iodinii comp. in this case not only agreed perfectly but strengthened digestion.

In cases of hard dry cough without any material physical signs continuing for some time, the cough was arrested in short order by the prompt administration of the remedy.

Cases of nasal catarrh, particularly those with reflex cough received marked benefit from the use of this combination.

The last stage of acute bronchitis which at times is difficult to eradicate promptly, was quickly dissipated by the use of this remedy.

Lately I have been treating cases of subacute and chronic gastritis by this means with apparently equal success. From observations made thus far, I expect to have as good results with this class of cases as with those of the air passages.

This remedy has been used quite extensively by my friends, Drs. A. H. De Young, Geo. Roessler and F. X. O'Neill, and their experience fully corroborates mine.

1333 Franklin St., Phila., Pa.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting, November 25th, 1891.

Dr. John B. Roberts read a paper on Clinical Contributions to Brain Surgery. (See page 5).

DISCUSSION.

Dr. M. Price:—I should like to ask a question, and that is in regard to the propriety of removing a clot in a case where the operation has been delayed for some time, and where, after trephining, it is found that the clot has become adherent, and where the attempt at its removal is followed by free bleeding. This question presented itself in the case of a young man injured in an ironworks in Phœnixville, some two weeks ago. A small stove shovel was thrown at him, the handle striking and penetrating the skull. For the first day or two there were no symptoms of paralysis. Dr. Shoemaker was called to the case a week or so after the

accident, and at once decided on operation, at which I assisted him. There was incomplete paralysis of the right side, and there had been some slight convulsive attacks. The trephine opening overlapped the clot and the depressed fragment of bone. As I have said, the clot was adherent, and the attempt at removal caused free bleeding. We allowed it to remain, thinking that this would do less harm than the violence necessary to remove it. So far, the result shows that we acted rightly, but what the final result will be I cannot say.

Some of you may recall two murder cases which occurred in 1873. They were both cases of penetrating wounds of the skull through the eyeball, produced by umbrellas. One was a man who, after the injury, came to the Fifth Street Dispensary, where I examined him. He then went to his home in Camden, where he died in a few days. The second case was that of a drunken woman, whom I saw four hours later. She was wounded by her husband in his attempt to ward off her blows. She was removed to the Pennsylvania Hospital, where she died.

Dr. T. S. K. Morton:—I did not understand Dr. Laplace to state that any provision for drainage was made at the time of the first operation. That might possibly have warded off some of the consequences of the injury.

I should like to ask those present their views and experiences as to the results of operations for epilepsy. It has been my fortune to see a good many cases of epilepsy operated upon, not only where the malady originated in the brain, but in other ways, as from phimosis, contracted tendons, neuralgic testicle, etc., and in none of these cases, if my memory serves me right, has there been a permanent cure. In one case, where a contracted tendo Achillis was divided, the seizures remained absent for two years and then returned. It has seemed to me that possibly the profound anæsthesia has something to do with preventing the occurrence of the attacks.

I had one case which was considered traumatic epilepsy, referred to me by Dr. Mills, of a child two years of age, who had fallen, striking its head on a piece of iron. Before the accident there had been no epileptic seizures; after the injury seizures soon began, and recurred with great frequency. A thousand convulsions were counted in a short time. These involved one side of the body, apparently beginning in the centres for the thumb, finger, and arm; extending down the right side; and subsequently becoming general. It was decided to apply a large trephine over the arm centre and see what was there. An inch and a half button was taken out. The dura was thickened, and I dissected it entirely away, leaving a margin of an eighth of an inch all around the trephine opening, so that hæmorrhage could be readily controlled. There being no apparent lesion of the brain, the œdematous pia mater was not opened. The button of bone was not replaced. The flaps were sutured, and catgut drain introduced. The drain was removed ten hours after the operation, when the dressings were found saturated with serum. The wound healed by primary union, and the child went home into the country on the tenth day. I understand that there has been no material improvement in his condition.

Dr. Charles K. Mills:—I can recall ten or twelve of my own cases of epilepsy in which I have had operations performed, and I have been present at fifteen or twenty other operations, so that I have a personal experience of some twenty-five or thirty cases of operation for epilepsy. I have also paid a good deal of attention to the theoretical part of the subject. I am sorry to say that the results in the majority of cases have not been permanently good, but I do not feel altogether discouraged in regard to cranial and cerebral operations for cases of this character. There are reasons why these operations have not succeeded. Some are inherent to the condition, while others are dependent upon errors of diagnosis, while still others are dependent upon the fact that the convulsive habit has been induced by the long continuance of the condition.

I have had two cases of cortical excision. One of these will be reported by Dr. Keen in the coming number of the *American Journal of the Medical Sciences.* In this case a small tumor was found in the centre of the trephine opening, which proved to be a sarcoma. A part of the cortex an inch in diameter was also removed. Although the patient improved after the operation, she is now practically no better than before the operation. It seems to me that in this case the brain and nervous system had been so influenced by the long-continued convulsions that they could not recover. The great difficulty in many of these cases is the late period at which the operation is performed. In nearly all cases of epilepsy, except those due to recent traumatism, the affection has

existed for some time. And then there are secondary changes which cannot be removed by trephining.

I think that of all cases certain classes of hæmorrhage present the greatest likelihood of benefit from operation. These are certain supra-dural and sub-dural hæmorrhages which can be pretty well localized. In the case of Dr. Price, I think that it would have been better to remove the clot as a whole, not perhaps by traction, but by a second trephine opening. In some cases these dural and sub-dural hæmorrhages do lead to permanent epilepsy, even though at first no symptoms are present.

I believe that the most brilliant results, although we have not had them yet, will be in cases of brain tumor. In this class of cases, fibromata offer more chance than other forms of growths, for usually they do not permeate the brain. Some old syphilitic tumors, and a few of other varieties, can be removed. The difficulty in these tumor cases is that they have been left too long.

Dr. James Hendrie Lloyd:—The cause of the paralysis of the arm on the same side as the tumor in this case seems obscure, but I inferred from what Dr. Roberts said, he was not himself certain of the accuracy of this observation. I can hardly see how that tumor could cause hemiplegia of the same side unless it acted as a cerebellar tumor sometimes acts—by downward pressure. In some tumors of the cerebellum there is hemiplegia on the same side from pressure downward on the metor tracts below their decussation. In this case the tentorium would probably prevent such downward pressure, and I hardly see how the alleged fact could be explained in this way. The brain has not been thoroughly dissected, and there may be some other lesion, as hæmorrhage or a secondary growth, which has caused this symptom.

Dr. Roberts:—I was much interested in Dr. Laplace's case, but I do not quite understand the condition of affairs. I understand that the temperature which had been high, had descended to about normal before the operation. I should like to know what was the character of the clot some two weeks after the accident. Was it broken down or partially organized? It seems to me that it would be difficult to get away an old clot of blood which would be ubrinous from such an irregular surface as the base of the skull. I could not help thinking that possibly the clot removed was one due to the manipulations at the base of the brain. Again, was the discharge from the wound serum from blood-clot, or was it cerebro-spinal fluid mixed with a certain amount of inflammatory exudate? While the result has been exceedingly brilliant, I could not help thinking that perhaps if no operation had been done the patient might still have recovered. As the history, as I remember it, seemed to indicate beginning improvement, was it absolutely necessary to keep the wound open for a number of days? I can understand that drainage is necessary in recent brain injuries, but in this case the drain was used at a late period and kept up for some time. The case is one of extraordinary interest, and I simply wish to have these points brought out clearly, as I failed to grasp the points when the report was read. No unjust criticism is intended, but I wish to study the case.

It seemed curious that in my specimen of brain tumor there should be right-sided hemiplegia, but I think that there is a little question that it was on the right side. I inquired in regard to the eyesight, and as far as known there was no blindness or deafness. Very few symptoms were noted, as the patient was in a public institution and made no complaint until a few days before her death. I would have been interested to hear in regard to the probability of the paralysis being due to pressure upon the longitudinal sinus damming back the blood and making secondary pressure, as it were, on the opposite side.

Dr. Laplace:—I would state in reply to Dr. Morton's question, that at the first dressing I put in an iodoform drain, which remained in until the time of the operation. In regard to the points suggested by Dr. Roberts, I would say that I was well aware that on the thirteenth day the clot would not be in the condition that it was on the second day. I knew that it would be fibrinous, and in order to entangle it I devised the little instrument shown.

A few hours after the accident the temperature rose to 104°, and then for the next ten or twelve days varied between 100° and 103°. The coma then began to increase. Because the temperature before the operation was low, it did not follow that the patient was getting well. The patient was really worse. He was more comatose and he could not swallow. He had to be nourished by the bowel. Something had to be done, or he would die. I relieved the intracranial tension and provided for drainage. There must be drainage in cerebral surgery on account of the unyielding nature of the cranial wall.

Selected Formulæ.

FOR LUMBO-ABDOMINAL NEURALGIA.

The following ointment is highly recommended for this affection:

℞ Salicylic acid.....grammes x.
Pulverized camphor..... " vj.
Vaselin..... " xlv.
M. Sig. To be rubbed frequently.

—*Il. Raccoglitore Médico*, November 20, 1891.

MIXTURE FOR SCIATICA.

The following mixture has been employed with success in the treatment of sciatica:

℞ Fluid extract of belladonna...grammes 1.81.
" " " aconite ..... " 5.60.
" " " gelsemium... " 22.00.
M. Sig. 6 to 8 drops every four hours for adults.

—*Il. Raccoglitore Médico*, November 20, 1891.

IN OBSTINATE VOMITING.

In the obstinate vomiting of certain dyspepsias, H. Guimbail recommends washing of the stomach with either of the following solutions:

1.

℞ Bicarbonate of sodium.....grammes iv.
Water..... " M.

2.

℞ Naphthol.....grammes 0.25.
Water..... " M.

—*Journal de Médecine de Paris*, November 22, 1891.

FOR CHAPPED NIPPLES.

In the treatment of chapped nipples Vinay has employed successfully the following formula:

℞ Aristol.....grammes iv.
Liquid vaselin..... " xx.
M. Sig. To be locally applied.

—*Le Bulletin Médical*, November 25, 1891.

INHALATION FOR WHOOPING-COUGH.

Beall recommends, as inhalation for the treatment of whooping-cough, the following mixture:

℞ Thymol.....grammes 1.20.
Phenic acid..... " 15.00.
Essence of sassafras.
Essence of eucalyptus.
Essence of turpentine.
Liquid tar, aa..... " 7.50.
Ether..... " 4.00.
Alcohol, q. s. for " 90.00.
M. Sig. About 30 drops of this mixture are placed on a handkerchief, and the child made to inhale it. This application is to be repeated every two or three hours.

—*La Médecine Moderne*, November 20, 1891.

NASAL DOUCHES.

In the ulcerated condition of the mucous membrane, occurring in the tertiary form of syphilis, the following formula is highly recommended by Ricardo Botey, to be applied in the form of douches:

℞ Pure chloride of sodium.....grammes cxx.
Crystallized phenic acid..... " vj.
Thymol..... gramme j.
M., and make twelve powders. Sig. A powder to be placed in two large glasses of luke-warm water, and the solution applied as indicated.

—*Archives Internacionales de Laringologia, Otologia y Rinologia*, December, 1891.

FOR CHRONIC PHARYNGITIS.

In this affection the following can be advantageously used:

℞ Ergotine.....gr. xv.
Tincture of iodine.....℥ j.
Glycerin.....℥ j.
M. Sig. To be applied three times a day by means of a brush.

—*L'Union Médicale du Canada*, December, 1891.

FOR ASTHMA.

The following mixture, to be inhaled during an asthmatic attack, is of value:

℞ Ether.....℥ j.
Essence of turpentine.....℥ iv.
Benzoic acid.....℥ iv.
Balsam of tolu.....℥ ij.
M. Sig. Applied as indicated.

—*L'Union Médicale du Canada*, December, 1891.

FOR CHRONIC GOUT.

For the local treatment of this rebellious malady, the following formula is recommended as being of great utility:

℞ Etheral tinct. of capsicum.
Spirits of ammonia.
Essence of turpentine.
Linseed oil, aa.....℥ j.
M. Sig. To be applied by rubbing.

It is also said to be of value in articular and chronic muscular rheumatism, and even in chronic bronchitis.

GASTRO-INTESTINAL ATONY.

Dr. Germain Sée (*Il Raccoglitore Medico*, No. 14, 1891), in gastro-intestinal atony with tympanites, uses the following:

℞ Magnesiæ ustæ } aa..... grammes xv.
Cretæ preparat. }
Colombo pulocrizat.....gramme j.
Pulv. vanillæ..... " 0.6.
A half teaspoonful before each meal.

Nux vomica tincture may be given in some cases instead of the above, with a saline purgative.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by postal note, money order or registered letter.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

LEADING ARTICLE.

THE NECESSITY FOR THE MORE GENERAL USE OF ABDOMINAL PALPATION AND PELVIMETRY IN OBSTETRICAL PRACTICE.

The conduct of labor in this country is empirical rather than scientific. This fact does not reflect so much upon the practitioners as upon the teachers of obstetrics. It has been a popular opinion that American women are so well formed, so vigorous, and healthy that labor with us is physiological, purely, and that much knowledge and certain rules of practice which are of value to the European practitioners are superfluous in our more favored country. This old, popular, soothing theory has been the cause of much lack of knowledge and careless rules of practice in this country, and indirectly has caused many deaths and has heaped dishonor upon our profession.

The fact is we have no such inhabitants as this theory assumes. Especially in our large centres people of foreign birth, or the children of foreigners abound; and our own women are far from physical perfection. Pelvic deformities are common, and are by no means confined to the foreign population.

Under the old rule of practice the practitioner made no special study of an individual pregnancy. He assumed, as he was taught, that all would terminate happily, "because labor is a physiological process." No reflections concerning the relation of the passenger to the passage disturbed his mind; when called to the labor, still no special study of the case was made. Even an arrest of the head at the superior strait did not give rise to questions other than dynamic. Tedious labor he ascribed only to rigidity of the soft parts, or to an unfavorable presentation, or to inertia. Labor not progressing, forceps were applied and traction made, often great and sustained traction. This failing, perhaps a friend was called who repeated the process with a like result. Not until this time was it considered necessary to study the pelvis, and but too often the practitioner was ignorant of the

methods of mensuration to be employed. The results of this method of practice in cases of pelvic deformity are but too well known to us. Perhaps a dead or spoiled baby was delivered after the greatest effort, the process inflicting bruises and lacerations on the exhausted mother. Or at the last, delivery was effected by embryotomy. Cæsarean section was rendered too dangerous to be employed except under absolute indications, the mother being exhausted as a rule before this was considered. And only too often septic infection and death of the mother as well as the child closed the scene.

Fortunately for our women and for the good name of American medicine a new era has dawned. Students at the present time are taught the anatomy of the deformed as well as of the normal pelvis, and the mechanism of labor peculiar to the several varieties of deformity of the pelvis. Abdominal palpation and pelvimetry also are taught, and the rule of practice laid down is, that all primiparæ should be carefully studied at least six weeks before term, so that any abnormality in the pelvis, or in the presentation of the fœtus may be known. And the same is true of multiparæ who have had difficult labor.

This rule of practice places the medical attendant on an entirely different footing. Each case of pregnancy and labor is one for scientific study. If but slight deformity is found, nature can be trusted to overcome the difficulty with perhaps minor assistance; if the deformity be considerable, labor can be induced at the thirty-fourth to the thirty-sixth week; or if the deformity be great, Cæsarean section can be determined upon and done at term as a formal operation with all the care usual to abdominal sections. On the other hand, if the pelvis is normal, as is the rule, practitioner and patient are reassured, since the only difficulties likely to be encountered are dynamic.

If only all practitioners would follow this beneficent rule American practice and results in the management of cases of labor in deformed pelves would cease to be a reproach. Especially could the percentage of craniotomies be decreased by timely resort to the induction of labor, or to the Cæsarean section, in proper cases, before the patient's chances for recovery are jeopardized by attempts at delivery by forceps or version.

The outlay of time in examining a patient by abdominal palpation and external pelvimetry is inconsiderable, and this is sufficient to separate the normal from the abnormal cases. Thus it is seldom necessary to make a vaginal examination. The benefit derived by the practitioner himself, more especially from the palpation, is inestimable. There is no better way of cultivating the *tactus eruditus*, so valuable to us all. Experience makes the results of external palpation quite exact, so that in the diagnosis of the preventation and position of the fœtus it becomes more valuable than the internal examination.

In time, undoubtedly, this practice will become general, but that day will be hastened, women in travail more surely relieved, and the good name of our profession conserved if every one who has followed the old system will familiarize himself with the principles of obstetrical abdominal palpation and pelvimetry, and apply them in his daily work.

Obituary.

E. B. P. KELLEY, M. D.

Dr. Edw. Bentley Perley Kelley was born at Campbellstown, Lebanon Co., Pa., 52 years ago. His early education was received at Strausburg Academy, and his medical diploma from Jefferson Medical College, at Philadelphia. After his graduation he was for a time connected with one of the Hospitals in the city of Philadelphia. Immediately upon the breaking out of the civil war he entered the Union Army as a surgeon, and was soon promoted to the rank of Brev. Lieut. Colonel, U. S. Volunteers; and later Colonel, and was Surgeon-in-chief, 1st Div., 1st corps, Medical Division, 6th Army Corps.

He was present at 52 battles and at the surrender of Gen. Lee, and was finally discharged in August, 1865. What a splendid

record of service to his country; no greater encomium could be needed. After leaving the army, he came to Perreniville, N. J. and entered into partnership with the late Dr. T. J. Thomason, and here he remained about 9 years. On the 15th October, 1873 he married Miss Frances Bulkley, of Cranbury, N. J., and July 24, 1874, settled at Perth Amboy, N. J., where he soon built up a large and lucrative practice. He died at his home, November 25, of cerebral hæmorrhage, after only a few hours illness, and never regained consciousness from the beginning of the attack.

Dr. Kelley was an excellent surgeon and a very skilful physician—two qualifications very rarely combined.

He was a kind husband and an indulgent father; a man of fine presence and a high-toned honorable gentleman.

He was the trusted advisor of hundreds of families, and by his many acts of genuine charity endeared himself to an unusually large circle of true friends.

He was a rigid observer of true medical ethics, and although he considered his first duty was toward his patient, no physician ever disliked to meet him in consultation.

He was a member of the Grand Army of the Republic, and was never absent from a reunion of the Army of the Potomac from the time of its organization.

He leaves a widow, one daughter and a brother to mourn his loss.

He was laid to rest in the cemetery of the Second Presbyterian church, at Cranbury, N. J., on Saturday, November 28th, 1891.

A delegation of Odd Fellows, Knights of Pythias and his G. A. R. Post were present.

J. C. Holmes, M. D.

Correspondence.

DR. MASSEY'S CASE REPORTED AT THE MEETING OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY, DECEMBER 12TH.

Editor Medical and Surgical Reporter:—I was unfortunately not present at the las meeting of the Philadelphia County Medical Society, the proceedings of which appeared in the Reporter of December 12th, but beg your permission to comment briefly on the final paragraph of Dr. Price's remarks in closing the discussion on his paper, as they appear on page 940.

It is not always possible to intelligently respond to the discussion on a paper that has taken a wide range, yet I know of few instances where the responder was so wide of the mark as when Dr. Price responded to Dr. Woodbury. The case referred to by Dr. Woodbury was treated by me by the intra-uterine or Apostoli method after a non-electrical exploratory puncture, and this was distinctly stated by him. In view of the brilliant result gained from this harmless treatment it is incomprehensible how the case can be regarded as a "proof of the value of operative treatment", or why we should be congratulated on not having a death instead of benefit, unless, as was doubtless true, the tenor of Dr. Woodbury's statement has been misunderstood. The evidence of Dr. Woodbury's case was strongly in favor of the electrical treatment of fibroid tumors, and as the readers of the Reporter can see the proof, in the shape of a well woman, any day, I should hate to have them think otherwise about it.

Yours truly,

G. Betton Massey.

THE TYPEWRITER MATTER.

To the Editor of the Medical and Surgical Reporter:—Having a considerable acquaintance with typewriters, and having done all my own work on the instrument for the last three years, I am inclined to think that Dr. Sherman is wrong about the machine being the cause of injury to the eyes, although I fully agree with him that stenographic writing is bad for weak visual organs. Several articles written by myself as to the value of the instrument in such maladies as writer's cramp, incipient paralysis, etc., were based on the ideas had from those who suffered from such troubles, and who were able to do their work with the machine, but not with the pen, and I might extend these remarks by showing, (if space permitted), that in precisely such disorders as eye-strain, the typewriter is a most valuable adjunct in securing a cure.

Now, it is not at all necessary to look at the keys when writing, and experts do not do so as a rule; the action of the fingers is almost automatic, as it is in playing the piano or organ. I seldom look at the keys of an organ when playing, the music taking the attention so far as seeing is concerned, in case the piece is played from notes. To try this fully, although I usually do not look at the keys of my machine except casually, I have written this without looking at them at

all, hence one or two slight errors may exist. Although not feeling in good shape for writing anything, I have done this at the best speed possible, as a matter of experiment, and not being an expert, it will be seen that the work can be done so as to save the eyes by one who cares to learn a little, instead of injuring them. In speaking of the apparatus I refer, of course, to reputable machines, not the small playthings which require constant inspection whilst writing with them, (or trying to do so.) Anyone who uses a "Remington", will find his eyes protected equally with his finger muscles, to say nothing of the time saved to himself in writing, and to his reader in deciphering what he wants to say.

The above contains about three hundred and fifty words, and was written in eighteen minutes, allowing a few seconds to run the ribbon back. The fact that one occasionally looks at what has been written does not militate against the machine, for we must do so when the pen is used, or the pencil; moreover, we actually follow the pen with the eye all the time we are writing. Maybe the doctor can find something wrong about the stomach or the eyes not due to the hard work he does with his typewriter.

Philadelphia.

Book Reviews.

SANDERS' QUESTION COMPENDS, NO. 21. ESSENTIALS OF NERVOUS DISEASES AND INSANITY: THEIR SYMPTOMS AND TREATMENT. A MANUAL FOR STUDENTS AND PRACTITIONERS. By John C. Shaw, M. D., Clinical Professor of Diseases of the Mind and Nervous System, Long Island College Hospital Medical School; Consultating Neurologist to the St. Catherine's Hospital, and Long Island College Hospital; formerly Medical Supt. of the Kings County Insane Asylum.

This brief synopsis of nervous and mental diseases contains much to commend it to the student and busy practitioner of medicine. Its arrangement is simple and consistent with the modern views of the pathology of the affections treated of, as far as possible. The author has wisely recognized the true scope of his work, and has not marred its real value as a synopsis by departing too far from the general outline of his subject. Each disease is regularly dealt with regarding definitions, etiology, symptoms, diagnosis, prognosis, and treatment. The forty-eight original illustrations, selected chiefly from the author's private practice, are well executed and add value to the work.

The portion devoted to Insanity is of particular interest to the student. Since it presents in a few words much valuable information regarding what is to most students a very obscure subject.

Necessarily only parts of some subjects could be presented, and indeed one is rather amazed to find nearly all the diseases of the nervous system and mind treated in one little book of 190 pages.

One feature seems misleading and inappropriate in a book of this kind. We refer to the incomplete bibliography which is attached to the description of various nervous diseases. The bibliography of hereditary chorea is an instance of this, and this feature of the book is a literary blunder. With this exception we heartily recommend this little volume to the student and the profession generally as a concise, readable and faithful synopsis of diseases of the mind and nervous system.

PERISCOPE.

THERAPEUTICS.

RESORCIN IN LARYNGEAL PHTHISIS.

Dr. Tymowsky publishes in the *Monatschrift für Ohrenheilkunde* a contribution to the treatment of laryngeal phthisis. He considers that when the hygienic surroundings of the patients are favorable, rest and liquid nourishment are sufficient to allow simple erosions and even superficial ulcers to heal. When the latter are of greater depth, and the surrounding tissue is infiltrated, cocaine and alkaline inhalations must be administered; and when the inflammation has been reached by this treatment, lactic acid in a solution of the strength of from 50 to 80 per cent., or an 80 per cent. solution of resorcin, may be applied successfully. Iodoform, to be useful, must be applied twice a day, and only when the ulcers are covered with abundant granulations. Dr. Tymowsky calls resorcin the most convenient of all these remedies, because it gives no pain, and need only be applied once a day. The solution must, however, be of the strength of 100 per cent. for unhealthy-looking ulcers which are undoubtedly of tuberculous character, when its effect may be depended on. At the same time inhalations of from 2 to 5 per cent.

solution of resorcin may be substituted for those of cocaine. Resorcin consequently is antipyretic, antiseptic, and hæmostatic, and may be given internally in quantities of three or four grammes a day. It is also used externally in various forms. Dr. Unna has administered it for a long time past in chronic recurrent ulcerations of the skin.

PHENOCOLL HYDROCHLORIDE IN MALARIA.

Prof. Albertoni, of Bologna, makes a very important communication, relating to the use of phenocoll hydrochloride in malaria. Prof. Albertoni states that he has carefully and extensively employed the remedy in his practice, and that the most excellent results ("I risultati sono bellissimi") were effected in a number of severe malarial cases. A comprehensive and highly eulogistic report has been prepared and will be published in an early issue of the "Academia Medica." This is highly valuable information; quinine has heretofore been almost the only available remedy for malaria, and even this occasionally disappoints. Phenocoll is already favorably known as a superior antipyretic and is also employed with success in the treatment of rheumatism.

THE SUBCUTANEOUS INJECTION OF ATROPIA AS A HEMOSTATIC.

M. Bierwirth (*Journal de Medecine de Paris,* October 25th, 1891) has obtained from the subcutaneous administration of from 3 to 6 deci-milligrammes [$\frac{1}{200}$ to $\frac{1}{100}$ grain] of atropia a prompt hæmostatic action in several cases of hæmorrhage, epistaxis and hæmatemesis, which ergotin and other unsual remedies had failed to control. The hæmorrhage was always arrested in about ten minutes. In one patient the injection had to be repeated three times; but in all the others one single injection sufficed to permanently arrest the loss of blood. Dr. Hausmann, of Méran, has also successfully resorted to the injection of atropine in hæmoptysis. Afterward, another German physician, Dr. Tacke, of Wesel, found atropia, hypodermically administered, an excellent method for the arrest of excessive menstrual loss.

The hæmostatic action of atropine is explained on the ground of an action directly the opposite of that pertaining to ergotin. While the latter agent causes contraction of the capillaries, atropia causes their dilatation by paralyzing the vaso-constrictor nerves, as has been demonstrated by Graham Brown. By increasing the quality of blood in the general capillary circulation, atropine diminishes the afflux toward the point of hæmorrhage, favors coagulation and arrest the hæmorrhage.

TUBERCULIN IN THE TREATMENT OF LUPUS.

Eichhoff (*Therap. Monatsh.*, Sept., 1891) relates his experiences extending over six months. Of twenty cases of lupus only one, occurring in a lad, aged 15, was completely cured, there being no relapse in six months' time, when the patient was last seen. In a second case of lupus acneiformis of the face in which the tubercle bacillus was found, a fresh set of lupus nodules appeared during the treatment. When, however, local treatment was combined with the use of tuberculin, the further development of these nodules was very slight, and the patient was discharged in five months' time with nearly all of them healed. Eichhoff would explain this by the reaction being insufficient to make a way through the skin, and thus time and opportunity were given for the absorption of the bacilli. This is the danger in the treatment, and consequently the lymph should be used in conjunction with local treatment. Of six cases thus treated two relapsed, and of four others treated with tuberculin alone three relapsed; of the remaining ten, part were discharged better and part were still under treatment. A case of prurigo and another of tuberculous eczema (Unna) were cured by the lymph. The lymph did not harm the patient in any case, and Eichhoff believes it to be a specific for lupus (tuberculous) processes, and that it does not act favorably on fresh tubercle. He says it is neither right to discard the remedy nor yet to look upon it as harmless, or as acting without fail.—*Brit. Med. Jour.*

LAVAGE IN VOMITING FOLLOWING CHLOROFORM.

Dr. Lienevitch (*Rev. Ther. Med. Chir.*) proposes to relieve the vomiting which follows the administration of chloroform, by lavage. He believes that not only the chloroform, but as well the irritation of the peritoneum produced by the antiseptics, is accountable for this symptom. He employs the tube of Faucher and washes out the stomach with warm water in which ½ to 1 per cent. of bicarbonate of soda has been dissolved, until the water returns clear. The

abdominal walls are compressed (after an operation of laparotomy has been performed) during the washing. The results are excellent, in that, if necessary, water sufficient for the needs of the patient can be left in the stomach. The general condition improves, because there is freedom from nausea, gaseous accumulations, vertigo, and epigastric distress.

SULPHAMINOL, OR THIO-OXYPHENYL-DIAMIN: A DISINFECTANT.

Dr. Wojtaszek communicates to the *Przeglad Lekarski* some observations he has made on sulphaminol, which has been brought out by an eminent German firm as a new disinfectant, which is said to split up with the body into carbolic acid and some compounds of sulphur. So far from this being the case, however, Dr. Wojtaszek found that large doses might be given to animals, both hypodermically and by the mouth, without producing any effect whatever; also that when applied as a dressing to cancers, soft chancres, and other open sores, it exercised no disinfectant action. He has therefore come to the conclusion that for therapeutic purposes it is inert.

TREATMENT OF BUBOES.

Dr. S. Cordier (*Ugeskrift for Laeger*, Nos. 4–5, 1891) punctures buboes as early as possible, injects a strong nitrate of silver solution into the cavity, and covers the place of puncture over with iodoform. Healing soon follows. Sometimes the puncture must be repeated.

TREATMENT OF INJURIES TO THE HEAD.

Dr. Senger, of Crefeld has proposed a new method of treatment with the object of facilitating repair in suppurating wounds of the head, with exposure of the cranium. He first arrests the phlegmonous and puriform process by surgical and antiseptic treatment —that is, by incisions, drainage, and dressing,—and so reduces the complicated injury to a simple cranial wound, which of course still produces a certain quantity of pus every twenty-four hours. A wet antiseptic dressing is then applied to the wound for two or three days, and when this is taken off the first layer of the tabula externa is removed with the help of a small chisel, in little scales, until drops of blood are seen in the bone. In from two to three days granulations protrude from the bone, and entirely cover it in from eight to ten days, and healing subsequently progresses as in other wounds. Suppuration ceases in proportion to the growth of the granulations. It is also possible to produce granulations by drilling several small holes in the external table until blood is seen; but the chisel is preferable, as it is difficult to estimate the depth of the drillhole, and the drilling takes more time than the chiselling. A still more serious objection to the former is that the holes get filled up with bone dust. In neither method is it necessary to give an anæsthetic, as but little pain is felt during the trifling operation.—*Lancet.*

OXYGEN INHALATION.

Neumann (*Therap. Monatsh.*, October, 1891) says that experiments up to now have been concerned with the inhalation of (1) as pure oxygen as possible with no increase of pressure, (2) a mixture of oxygen (63 per cent.) and nitrogen under ordinary pressures and (3) air with high percentage of oxygen and with increased pressure, and the authors communications refer to this. The following conditions must be present: (1) the production of the gas must take place in a manner which can be observed and regulated, (2) the amount of gas must allow itself to be approximately calculated with each respiration, (3) it must not irritate, and therefore (4) it must be mixed with air, and (5) it must be inspired under a moderately increased pressure. The author then describes his apparatus. Patients soon learn how to use it. The pulse, at first quickened, is ultimately slowed. No unpleasant head symptoms arise. There is no palpitation; in fact, the heart's action is regulated. Sleep is often induced, even in men. In many patients the night's rest has been improved, the breathing has been rendered easier, and there has been a general feeling of increased strength. In three cases treated at the same time by Koch's method, the fever disappeared in two, and was lessened in the third. The author thinks the action of certain drugs as of iron in chlorosis, may be increased by oxygen inhalation. He has treated very severe cases of anæmia, a case of convalescence from pleurisy, cases of phthisis, and a case of sepsis and of diabetes, with good results, and he appends a few notes on them. Neumann thinks it may be of service in gout, as it diminishes the amount of uric acid in the urine.—*Brit. Med. Jour.*

ANTIPYRIN IN AFFECTIONS OF THE PHARYNX AND LARYNX.

M. E. Saint-Hilaire (*Archives de Laryngologie*, September, 1891) refers to a recent paper by himself and M. Coupard, in which they described the therapeutic value of antipyrin, applied locally, in certain throat affections. By its means they were able to cure a variety of complaints dependent on undue sensibility of the pharynx and larynx, such as spasmodic cough, sensations of pricking in the throat, or of a foreign body, etc. These results seemed due to a local anæsthetic effect of antipyrin, and M. Saint-Hilaire has performed numerous experiments with the view of determining the anæsthetic properties of antipyrin. He draws the following conclusions from these experiments: 1. The anæsthesia produced by cocaine is complete, and applies to tactile sensation and to sensations of heat and cold. 2. The anæsthesia lasts from one to two hours. 3. In order to produce this effect the strength should be not less than 30 per cent. The solution employed by M. Saint-Hilaire is of a strength of 40 per cent. He thinks that antipyrin will be found especially useful in cases where a prolonged analgesia is desired; thus, in tuberculous ulceration, the pain may be kept under by painting the parts with the antipyrin solution two or three times a day. It will be found useful in those affections where either the reflex element or the painful element predominates. Moreover, antipyrin possesses an antiseptic property which will render it additionally useful in certain cases. Of course, when for the purpose of operation an anæsthesia of short duration is required, cocaine is preferable, as the effect is more rapidly produced, and is more complete while it lasts.—*Brit. Med. Jour.*

ON THE THERAPEUTIC VALUE OF NERVE-STRETCHING.

Dr. Archimede Mischi comes to the following conclusions:

1. Nerve-stretching constitutes, by its manner of action, a special therapeutic process. This influence is felt even as far as the nervous centres and in the medulla oblongata in particular. A paralysis of sensation, with relative conservation of motility, is produced.

2. Nerve-stretching is an efficacious method of treatment in those cases in which the lesion is peripheric; hence, it is useful in the treatment of the various neuralgias, tic-douleureux, spasms, traumatic contractures and reflex epilepsy.

3. It must be condemned in tabes dorsalis and various affections of the medulla oblongata, in which it is never successful, often injurious and, finally, sometimes fatal.

4. It offers but the slightest probability of success in the treatment of tetanus.—*Il Raccoglitore Medico*, Dec. 10, 1890.

CRESOL SOLUTIONS.

The question of securing a neutral solution of the cresols has been the subject of recent investigation, the custom of emulsifying them by means of soap or alkalies, being open to many objections. It has been ascertained (*Chem. Zeit.*) that the addition of cresol to a very concentrated aqueous solution of sodium salicylate, produces a mixture which may be diluted with water without fear of the cresol separating on standing. This process does not result in the formation of any double salt. The ortho-meta or para-cresol may be used, and the sodium salicylate may be replaced by salicylates of other bases or by the salts of ortho-oxybenzol carboxylic acid, or of the phenols and naphthols, the latter possessing the solvent property in a greater degree than the former. Experiments demonstrate the superiority of solutions effected by means of sodium cresotinate. A ½ of 1 per cent. solution is said to be equally as efficacious for bactericidal purposes, as a 5 per cent. solution of carbolic acid, and to be free from its caustic and irritant effects.

MEDICINE.

OXALURIA AND HÆMATURIA.

Dr. Francis D. Boyd writes in the *Lancet* that very little is known of the clinical significance of the excretion of oxalate of lime in the urine in the condition described as oxaluria. Numerous cases of so-called cyclical albuminuria, accompanied by oxaluria, have been described, in which by some authors the albumen was ascribed to irritation of the kidneys by the crystals of oxalate of lime. That some of the albumen in those conditions is derived from the urinary tract is highly probable, but the following case seems to support the view that the excretion of crystals of oxalate of lime does irritate the kidneys in some cases.

Mrs. M——, a young woman of a very rheumatic history, was taken ill during the night of July 20th with severe pain in the

lumbar region. She likewise had headache and felt very feverish. Next morning the pain was easier, though the headache was still present, and she noticed that her urine had become of a bright red color. There was no pain on micturition. He saw her on the following day; she was then complaining of headache. Pain in back still present; no œdema. First sound of heart loud and accentuated. Pulse 100, full, and of rather high tension. Urine faintly acid, containing blood in large quantities and albumen. Under the microscope the deposit was seen to be composed of blood-corpuscles, crystals of oxalate of lime, and numerous tube casts containing epithelial and blood cells, oxalate as well as crystals. On inquiry he found that for three days before the attack the patient had been partaking largely of rhubarb, which she said she knew never suited her. She was directed to take nothing but milk, to rest in bed, to keep the bowels freely open with Friedrichshall water, and nitro-hydrochloric acid was prescribed. On the following day there was marked improvement. The pain in the back was gone, the blood and casts were decidedly diminished, and urine was passed in larger quantity than formerly. The oxalates were still present. By July 26th the blood, albumen, and casts had entirely disappeared, and the patient was feeling quite well.

In the *Monthly Journal* for August, 1849, Begbie describes certain cases of what he terms the oxaluric diathesis, but in none of his cases, though there was pain in the back, does there seem to have been kidney irritation produced. The passage of the oxalates in the case above quoted differ from his, in that the oxalic acid seems to have been absorbed directly from the stomach, and not to have been produced during the process of digestion and assimilation. That there was in this case a true nephritis he thinks there can be no doubt from the presence of the casts, and the oxalate of lime crystals seem to be the cause, and not a mere concomitant.

PRIMARY SPLENOMEGALY.

M. Bruhl (*Archiv. Gén. de Méd.*, June, 1891) describes the disease first called splenomegaly by Professor Debove, and characterized by (1) hypertrophy of the spleen; (2) progressive anæmia without leukæmia; and (3) absence of glandular enlargement. It may begin with general symptoms of anæmia, with pallor, fatigue on the least exertion, and debility not unlike Addison's disease. More rarely it commences with pain in the left hypochondrium, nausea, vomiting, and even obstinate diarrhœa. These attacks of pain, except for the locality, resemble hepatic colic. They are due to a perisplenitis. The spleen is enlarged, somewhat tender, and the surface slightly irregular. Frequently there is a pleurisy of the left base. But even in the second group of cases, a history of previous weakness, loss of color or epistaxis can generally be made out. When the disease is fully developed the anæmia is not essentially different from other forms of anæmia. Examination of the blood reveals nothing that is pathognomonic. The red cells are much diminished in numbers, and the amount of hæmoglobin may be reduced to one-half. In most cases the number of white cells is not increased. No micro-organisms have been found. The enlargement of the spleen is progressive, uniform, and considerable. Sometimes the liver is enlarged. There may even be an interstitial hepatitis. Digestive troubles and constipation are usually present. Hæmorrhages do not often occur. Epistaxis is the most common, and, in the advanced disease, petechiæ may be present, especially on the legs. The observations on the urine are few and discordant. The glands are not enlarged, except on occasional slight hypertrophy of the mesenteric and retro-peritoneal glands. In the last stage of the disease cachexia is present; the appetite is lost; there may be diarrhœa and hæmorrhages; fever is exceptional. As to the course of the disease, it lasts from six months to two years, advancing steadily to a fatal end. Sometimes, however, it progresses by fits and starts, and rarely there may be an amelioration or even a quasi-recovery. M. Bruhl says that surgical interference (splenectomy) has brought about a complete cure. The complications are pneumonia, perisplenic abscess, and perforation of an ulcer of the stomach or intestine. Splenomegaly must be distinguished from leukæmia, from tumors of the spleen, from amyloid disease, and from the enlarged spleen accompanying cirrhosis of the liver. In the grave forms of anæmia the spleen is rarely much enlarged.—*Brit. Med. Jour.*

SYPHILITIC DISEASE OF THE LUNGS.

Dr. Haslund distinguishes two forms of pulmonary syphilitic disease: 1. The diffuse form—an increase of the interstitial connective tissue. The affection always begins at the root of the lung and extends thence 2. The gummatous form—one or many gum

mata scattered through the lung, except the apex, which is rarely affected. Both forms often coexist. The course of the disease is sometimes very rapid, death occurring in from two to six months. In other cases the disease causes no symptoms, and the presence of pulmonary disease may be discovered only at the autopsy. In the early stages there are no physical signs; later on, in some cases, dulness on percussion over the root of the lung is noticed, and inspiration becomes rough and sharp. Toward the end respiration acquires a cavernous character. Syphilitic lung disease is difficult to diagnosticate during life. The distinction from phthisis is difficult. The diagnostic points on which Professor Haslund relies are: 1. Absence of tubercle baccilli. 2. Location; the apex is rarely affected in syphilis, almost always in tuberculosis. 3. The downward progress of the case is much more rapid in syphilis without appropriate treatment than in phthisis. 4. Absence of fever in the earlier part of the disease. 5. History of syphilis. 6. Results of antisphilitic treatment. The prognosis is good if suitable treatment (mercury and iodide of potassium) be adopted in time. The disease is rare. Professor Haslund has, however, diagnosticated and successfully treated several cases.

THE BACILLUS OF ENTERIC FEVER.

In the *Centralblatt f. klin. Medicin*, September, 1891, Dr. Lehmann, when speaking of the recent contributions by Dr. Babes and M. Cassedebat to this subject, says that comparatively a short time ago a fairly sure recognition of the typhoid bacillus, even outside the body, seemed a task easily to be performed by the help of the culture on the potato, but that now it must be looked upon as very difficult, if not impossible. When this difficulty was recognized, other distinctive signs were sought for, as, for instance, the negative indol reaction, the growth on colored media, or upon potato gelatin, but none of them are really characteristic. M. Cassedebat (*Ann. de l'Institut Pasteur*, 1890, No. 10) found three kinds of bacilli resembling that of enteric fever in the Marseilles drinking water. He thought he could distinguish them by the color of the inoculation into gelatine, by the behavior of old bouillon cultures, and by the growth in colored media. Dr. Babes (*Zeitschrift für Hygiene*, Band ix, Heft 2), on the other hand, would seem to be no longer in a position definitely to separate the nineteen varieties he obtained from the bodies of individuals dead of enteric fever, since he adds that in several of the varieties the tendency to lose many of their characteristics has been observed.—*Brit. Med. Jour.*

SPINAL SYMPTOMS OF GONORRHŒAL ORIGIN.

Drs. Spillman and Haushalter (*Revue de Médecine*, August, 1891) reports two cases in which spinal symptoms were associated with gonorrhœa. In each case the sequence of events was (1) pregnancy, (2) vaginitis contracted in the later months, (3) pains and swelling of joints, especially of the knee, (4) normal labor, (5) the onset of nervous symptoms. These were violent lancinating pains in the extremities, tingling of the feet, great muscular atrophy; the sphincters were not, however, affected, neither was the sensibility to pricking, touch, or heat impaired; the reflexes also remained intact. A bedsore formed rapidly on the sacral region. Under treatment, however, all these alarming symptoms disappeared, and even the atrophy of the muscles was almost entirely removed by a course of massage, etc. The authors are inclined to think that the knee swelling was secondary to spinal lesions.—*Brit. Med. Jour.*

SCLERODERMA.

From clinical obervations in three cases and a post-mortem study of one, Dinkler, (*Deutches Archiv für klin. Med.*, Bd. xlvii., H. 5 u. 6) maintains that scleroderma is a disease *sui generis*, characterized at the outset by firm swelling and at a late stage by cicatricial-like atrophy of the cutis. The swelling is frequently preceded by vasomotor disturbances. Pigmentation and desquamation may take place, but are not distinctive. Scleroderma may be diffused or circumscribed. The disease process is not restricted to the skin; it may appear in the brain and in striated muscular tissue. The etiology of the disease is obscure; the affection may appear spontaneously or it may follow acute or chronic injuries. It is anatomically characterized by hyperplasia of the connective tissue and by vascular changes. The disease of the vessels involves only individual arterial branches and corresponds to periarteritis, mesarteritis and endarteritis. Clinical observation and anatomical investigation render it probable that the disease is dependent upon an inflammatory process especially involving a varying arterial distribution. The prognosis is dubious. Treat-

ment must be constitutional, conjoined with the application of the constant current and warm baths.

SURGERY.

NEW OPERATIONS ON THE PROSTATE AND BLADDER.

Küster read a paper on this subject before the Deutschen Gesellschaft für Chirurgie, 1891, which is abstracted in the *Centralblatt für Chirurgie*, 1891, No. 26. After referring to Kümmel's method of operating by suprapubic cystotomy for enlargement of the prostate, he states that the researches of Von Dittel have shown that the obstruction to the flow of urine comes more often from the lateral lobes than the median, and that these can be better reached from the perineum than from above the pubis. Küster has operated three times, making his incision in the median line of the perineum and then transversely around the left side of the anus. There is great liability of wounding the urethra, and this occurred in two of his cases. It can, however, by care be avoided. In one case a fistula remained which has not yet closed. All three patients can void their urine in a stream and are very much improved. The permanency of the benefit cannot be determined, as the time which has elapsed since the operations is only from two to ten months. He also performed a total extirpation of the prostate and bladder in a man, aged 53 years, affected with carcinoma of the prostate with papillary degeneration. The patient was placed upon Trendelenburg's support and the bladder exposed above the symphysis. The upper edge of the pelvis was chiselled away, as advised by Helferich, and the bladder was opened to confirm the diagnosis, the cut being again sewn shut. With a blunt instrument the bladder was freed from the surrounding parts and an opening into peritoneal cavity closed with sutures. A median incision was made in the perineum and the urethra divided and the prostate separated with blunt instruments and scissors. In order to find the ureters more surely, the bladder was again opened. After they were exposed they were loosely tied and cut obliquely upward and backward. A few strokes of the scissors then freed the bladder. A male catheter was introduced into the rectum and an opening made. The mucous membrane of the ureters was sutured to that of the rectum, the knots being placed in the bowel and additional catgut sutures inserted. The wound was tamponed. The patient, who had had bronchial catarrh previous to the operation, died of a lobular pneumouia. The catgut sutures of the ureters gave away too soon and allowed urine to flow through the wound. Küster was induced to perform this operation by the success which he had in the treatment of a case of vesico-vaginal fistula by Rose's method. He made a fistulous communication between the vagina and rectum and then closed the vagina. The patient was thus enabled to retain the urine for two hours in the rectum — *Univ. Med. Mag.*

SUBMUCOUS RESECTION OF THE INTESTINE.

Dr. Kummer finds that the chief fault of the ordinary suture of the intestine is its tendency to cause a stenosis, which may be followed by intestinal obstruction, perforation, or paralysis. To remedy this disadvantage he has undertaken experiments on animals, and was led to adopt the following method: He dissects a cylindrical flap of mucous membrane, about 1½ cm. long, from the transverse section of the gut, and then unites mucous membrane with mucous membrane. The sero-muscular flaps are folded back in such manner that the serous margins are approximated, and sutured in this position. The sutures which in the ordinary Lembert suture protrude into the gut are placed on the outside of the intestine and thus do not narrow the lumen.— *Centralbl. f. d. gesammte Therapie*, August, 1891.

SPECTROSCOPIC EXAMINATION OF THE BLOOD IN SURGERY.

At the recent French Surgical Congress M. M. Henocque and Bazy reported the results of a series of examinations of the blood with the spectroscope made on persons who were compelled to undergo surgical operations. According to these investigations the demonstration of the quantity of hæmoglobine in the blood affords the surgeon some valuable information in cases where it is necessary to decide whether the patient's health is sufficiently good to permit of the performance of an operation which may not be urgently required. In ovariotomies and laparotomies undertaken for the removal of tumors it is of advantage to determine the degree of anæmia and the condition of nutrition by this method, so that the operator may be able to select the most favorable time for operation.

The authors also made some exceedingly interesting experiments with the view of studying the effects of chloroform anæsthesia upon the quantity of oxy-hæmoglobin in the blood and upon tissue metamorphosis. These investigations were carried on before, during and after the performance of surgical operations. It was demonstrated in eight cases of major operations that chloroform actually tends to augment the quantity of hæmoglobin in the blood, unless a condition of asphyxia is produced, and that this quantity may remain stationary despite severe losses of blood. One of the constant effects of chloroform anæsthesia, however, is to retard the reduction of oxy-hæmoglobin; that is to say, it decreases tissue metamorphosis. These phenomena therefore illustrate that chloroform does not exert a toxic influence on the blood, although it has a marked effect in retarding the vital chemical processes in the body. In cases of sudden death at the commencement of chloroform anæsthesia a complete arrest of tissue metamorphosis takes place, and to this, in the authors' opinions, should be attributed the extraordinary severity of this form of syncope. They also believe that these facts demonstrate the advantage of determining before operation whether an individual tendency to retarded tissue metamorphosis be present.

In our last year's August number we commented upon some experiments of Prof. Mikulicz relating to the same subject. In striking contrast to the results obtained by M. M. Bazy and Henocque, however, Dr. Mikulicz found that the prolonged administration of chloroform produced a decrease of hæmoglobine even in operations unattended with loss of blood. This fact simply illustrates the wide discrepancy in the results obtained by different investigators of the same subject.—*Internat. Jour. Surg.*

COMPRESSION OF THE CAUDA EQUINA—REMOVAL OF A TUMOR—RECOVERY.

Laquer reports in the *Neurolog Centralblatt*, 1891, No. 7, the case of a young man, aged 19, who had been suffering since September, 1888, from violent pain in the sacral region. The patient himself localized the pains from the very beginning in the interior of the sacral bone. At night, and frequently during the day, after long continued sitting and standing the pains become more violent. Finally he had to abandon his work, but absolute rest, careful treatment and various remedies failed to procure relief. Status in December, 1889: no impairment of motor power or of sensibility, no muscular atrophy; electrical reactions, deep reflexes, vesical and rectal functions normal; no incoördination. The dull, piercing pains were so acute at night that they deprived the patient of sleep; they irradiated occasionally on the posterior surface of the thigh down to the fossa poplitea. Galvanic treatment and chloral gave much relief, so that the original diagnosis—neuralgia of the plexus sacralis, perhaps neuritis—seemed corroborated. But in March, 1890, the pains returned and in September very large doses of chloral and morphine were of little avail. At that time the principal symptoms were: strictly localized pain in the middle of the os sacrum, pain on pressure at the same spot; both musculi recti femoris weak and slightly atrophied; transient paresis of bladder and rectum; the knee-jerk abolished on one side and very faint on the other; sexual functions feeble; decubitus on the right trochanter; complete absence of all inflammatory changes in the vertebral joints and in the bones; no R. D. Due consideration of the symptoms and the exclusion of any disease originating in the rectum or the pelvic organs led to the diagnosis of compression of the cauda equina caused by some neoplasm in the canalis sacralis. Dr. Rehn, having opened the sacral canal from the hiatus sacralis almost to the last lumbar vertebra, corroborated the diagnosis; for he found a soft tumor of the thickness of the little finger extending from the middle of the sacral bone into the vertebral canal; the tumor was extradural, not adherent to roots or to the dura mater, but it had exerted a strong pressure on the cauda equina and the dura. Weigert showed the tumor to be a lymph-angioma cavernosum. Status three months after the operation: The pains in the back have disappeared completely. The patient sleeps three or four hours in the night without an hypnotic. Occasionally there are slight pains in the left sciatic nerve. He walks for three or four hours without fatigue. No vesical or rectal trouble. The knee-jerks are easily elicited and are equal on both sides.

GYNÆCOLOGY.

GONORRHŒA IN THE FEMALE.

Bumm (*Centralblatt für Gynäkologie*, 1891, No. 22), from a long study of this subject concludes that gonorrhœa in women is a process limited to the superficial layer of the

mucosa ; the cocci invade the epithelial layer, but are always arrested when they reach the submucosa. The epithelium is originally cast off by reason of the active suppuration, but is quickly renewed, assuming the pavement form; after this change has occurred the active invasion of gonococci is usually arrested, but they continue to grow in the secretion, in which they may persist for months and years. The gonococci have no connection with septic processes; they do indeed cause suppuration of the mucosa, but are destroyed when they reach the subjacent connective tissue. If sepsis develops it must be in consequence of mixed infection; septic germs are frequently present in gonorrhœal pus, and a favorable nidus for the reception of external germs is offered by the purulent genital secretion. The urethra and cervical canal are the favorite seats of gonorrhœal infection ; acute gonorrhœa of the cervix gives rise to symptoms only at the outset, but after it has become chronic it may exist for years without causing disturbances, unless it extends to the corpus uteri and thence to the tubes.

The cocci possess no power of spontaneous movement and extend only short distances by proliferation. Extension over larger surfaces must be through the agency of the secretion. Normally the cervical secretion cannot pass the os internum, which also serves as a barrier to the entrance of the specific infection. Menstruation favors the admission of cocci into the uterine cavity, also certain mechanical causes, such as coitus, the introduction of sounds and intrauterine medication ; lastly, this is liable to occur during the puerperium. After they have reached the cavity they again remain stationary, and probably are only carried into the tubes from the causes already mentioned, the puerperium being the most favorable time, as the proximal openings of the tubes are then more patent. In fifty-three patients with gonorrhœa, who were kept under observation for at least five months after the initial symptoms developed, the cervix was infected in 75 per cent., the corpus uteri in 15 per cent., and the tubes in only 3.5 per cent.

PRIMARY CANCER OF THE CLITORIS.

Dr. F. J. Merkle (*Centralbl. f. Gynak.*, October 3rd, 1891) observed this disease in a woman, aged 61. At the site of the clitoris was a tumor of about the size of an apple, already beginning to break down. There was an indurated gland as big as a walnut in the left groin. The tumor of the clitoris was removed by means of the thermocautery. The patient died seventy-three days after the growth was removed. At the necropsy epithelioma of the clitoris, with metastatic deposits in the lymphatic glands, was discovered. Dr. Merkle believes that the clitoris was most probably the seat of the primary disease in this case.

REMOVAL OF OVARIES FOR EPILEPSY.

F. Howitz and Leopold Meyer (*Gynäk. of Obstetr. Meddel.*, vol. viii, parts three and and four, 1891) describe four cases. The results are, on their own admission, discouraging. The cases were under observation for from two and three-quarters to four years. In all the ovaries were more or less diseased. In one case only was the patient cured. The fits increased during pregnancy. In the second the same symptom was observed, but after the operation the patient's condition was but slightly improved. In the third and fourth no improvement followed lactation, yet in the third the epileptic fits had always increased in number and severity during catamenial periods, and from thirteen months after the operation no show ever appeared. In the fourth the fits had ceased for four years, and recurred when the patient was suckling. All the four patients had been subject to fits for over seven years, the first or successful case having been epileptic for thirteen years at the least. In three out of the four complete amenorrhœa followed the operation. In the third there was a typical irregular hæmorrhage from the sixth to the thirteenth month after the oöphorectomy.—*Brit. Med. Jour.*

OBSTETRICS.

LABOR IMPEDED BY PARASITIC FŒTUS.

Dr. Westerschulte (*Nouvelles Archives d' Obstét et de Gynéc.*, August 25th, 1891) was called in to a labor case by a midwife, who could not deliver the child though its head was already born. He found that the child was half born, its trunk being exposed as far as the umbilicus. He relaxed the cord and then attempted to extract the child, which was still living and had passed the seventh month of intrauterine life. Though he used much force the trunk remained fixed, and he began to suspect twin pregnancy with adhesion of the twins. He placed the patient across the bed, and on careful exploration detected a soft mass

behind the breech, which felt like a second bag of waters. After firm traction for about a quarter of an hour the child was suddenly delivered. It made a few feeble respiratory efforts, but could not be kept alive. A big cystic body hung down from the child's breech; it was double the size of the head, and contained a placenta-like structure and a piece of cartilage an inch and a half long. The child was a well-formed male; there was no anus, the rectum opening into the cyst, which clearly represented a parasitic fœtus. —*Brit. Med. Jour.*

THE TREATMENT OF POST-PARTUM HÆMORRHAGE BY MEANS OF THE DUHRSSEN UTERINE TAMPON.

In the *Therap. Monatshefte* Dr. Everke writes that post-partum hæmorrhages are either due to lacerations of the vaginal mucous membrane and cervix, or else they arise from the uterine cavity when this organ does not contract firmly after expulsion of the fœtus (atonia uteri). The hæmorrhages of the first variety can always be controlled by sutures, but the cases of uterine atony in which no effect is produced by using ergotin, compression, or rubbing with the hand require other treatment. Dührssen's method of using the tampon is the surest, simplest, least dangerous, and most readily carried out of all the methods. The technique is as follows; The hair about the pubes is to be carefully scrubbed with soap and water, the vagina washed out with a thirty-per-cent solution of carbolic acid or a sublimate solution of one to one thousand. For tamponing we employ from three to six metres of ten-per-cent iodoform gauze, eight centimetres wide. The left hand grasps the uterus and presses it downward; then (when no speculum is employed) the gauze is pushed up through the cervical canal with the right hand (employing two fingers) to the fundus. In a short time we feel a board-like contraction and the hæmorrhage ceases. The tampon is removed at the end of twenty-four hours. The author explains the action of the tampon in this way: that the raw material produces an irritation of the uterine muscle, the contracting organ presses its walls firmly against the tampon, the lumen of the vessels becomes closed, and the hæmorrhage ceases. (It is consequently not advisables to tampon the uterus too firmly). The tampon may also be employed in cases of puerperal hæmorrhage and in slight lacerations.

MORRENIA BRACHYSTEPHANA—A NEW GALACTAGOGUE.

Senhor Pedro N. Arata describes (*Revista Farmaceutica*, Buenos Ayres, No. 5, 1891) the chemistry and properties of the above plant, which is a member of the *Asclepiadaceæ* growing in the Argentine Republic and other parts of America. An infusion of the roots has long enjoyed a local reputation as a galactagogue, and the author has endeavored to determine the active principles to which such action may be due. For this purpose he made the following examination: (1) Extraction with ether: Nothing but a small quantity of chlorophyl, fatty acids, and resin could be obtained by prolonged maceration of the powdered root with this solvent. (2) Extraction of residue by alcohol: An alcoholic extract of the remaining root was made. Of this a portion (resin) was insoluble in water, the remainder forming a red solution, which contained malate of calcium, chlorides of potassium and sodium, and a substance giving alkaloidal reactions with the ordinary tests. No volatile alkaloids were found, the only other noteworthy substances separated being starch, albumen, and gum. By the Stas-Dragendorf method the alkaloid could be obtained as a dark reddish mass, of pleasant odor and very bitter taste, soluble in chloroform, water, and amylic alcohol. An accurate analysis of this substance could not be made owing to the small quantity available. (3) Active principles of the fruit juice: From the expressed juice of the fruit there could be obtained small quantities of the same alkaloid together with a glucoside. This latter substance is probably closely allied, though not identical, with a glucoside isolated by List from *Asclepias cyriaca*. The author does not appear to have yet worked out the physiological action of either of these substances, but, from an experience with a fresh infusion of the root, he is inclined to believe that the plant has valuable galactagogue properties.—*Brit. Med. Jour.*

PÆDIATRICS.

IODOFORM VAPOR IN WHOOPING-COUGH.

At a meeting of the Société Médicale des Hopitaux on July 17th (*Rev. Gén. de Clin. et de Thér.*, July 22d, 1891), M. Chantemesse read, in the name of Dr. Chibret, of Clermont-Ferrand, a communication on the

effect of iodoform vapor in the treatment of whooping-cough. The method consists in sprinkling the room in which the patients live with iodoform. Under this treatment, children presented a marked diminution in the frequency of the paroxysms, and the duration of the disease was shortened. No symptoms of poisoning were observed.—*Brit. Med. Jour.*

TREATMENT OF DIPHTHERITIC AND DIPHTHEROID CONJUNCTIVITIS.

Abadi (*Rev. Mens. des Mal. de l'Enf.*, August, 1891) writes that in the literature concerning the treatment of ophthalmia there is nothing precise which is to be found. Some advise the use of nitrate of silver, others warm, and others iced compresses. Others still recommend a great variety of antiseptic solutions. In most cases the eyes have been lost, cures being exceptional. Since Fieuzal and Coppez recommended the use of lemon-juice for this disease, the author has frequently made use of it, and always with satisfactory results. It was used fearlessly, for it was believed to be harmless to the cornea. During the three or four days in which the disease is most threatening it must be used every five hours, night and day. Subsequently the intervals can be lengthened to eight, then to twelve hours, and then it can be discontinued altogether. This treatment is useful not only in pure diphtheritic forms of the disease, but also in the diphtheroid forms. It is believed that nitrate of silver is very injurious in the treatment of this disease.

CLINICAL AND BACTERIOLOGICAL STUDY OF SCARLATINOUS ANGINA.

In a careful and conscientious thesis, Dr. Bourges divides the angina of scarlet fever into the erythematous variety, which may or may not be accompanied by a pultaceous deposit, the pseudo-membranous and the gangrenous forms. The pseudo-membranous may be subdivided into precocious or tardy, the first of which is often benign, does not extend, and produces little or no effect upon the general condition. Late pseudo-membranous angina, on the contrary, would seem to be most often of diphtheritic character, although the occurrence of very benign examples leaves this point doubtful, and a decision can only be reached by bacteriological investigations. The gangrenous form is the most severe, and is accompanied by special characteristics.

His experiments with the inoculation of streptococci found in scarlatinous angina have led him to conclude that "the anginas of scarlatina are due to a secondary infection by pyogenetic streptococci in the erythematous angina, in most cases of precocious pseudo-membranous angina, and in certain cases of tardy pseudo-membranous angina." The streptococci found in the suppurations which so often complicate scarlatina generally enter the system through the tonsils, which are infected from the beginning of the disease.—*Revue de Laryngologie*, etc., Aug. 1st, 1891.

HYGIENE.

SANITARY TRIUMPHS.

In an interesting article in the June issue of the American Statisical Association's quarterly publication, we find some significant facts regarding the advantages of sanitary legislation experienced in England within the past sixteen years. In the year 1875 a general law was passed in England for the protection of the public health, known as the Public Health Act, and from that time the death rate in England has decreased for all diseases which owe their origin and growth to defective drainage and impure water supply. Typhoid fever is such a disease, and the diminution of 57 per cent. in the death rate from this malady is undoubtedly the greatest triumph for sanitary reformers. During the ten years from 1866 to 1865 the annual mortality was 22.19 per thousand inhabitants; and from 1838, the first year of careful registration, to 1865, the average annual rate was about 22.35 per thousand. But for the ten years of the period 1880 to 1889 the average falls to 19.08. It seems justifiable to ascribe this diminution in the death rate to the operation of the Public Health Act, and the execution of duties such as drainage, inspection of water-supplies, vaccination, and others which are becoming better understood. Mr. Farr, in his *Vital Statistics*, estimates the value of human life in England to be about $770 a head; that is, the value inherent in the people as a productive money-earning race. If we suppose, which is allowable if other things remain the same, that this diminution of the death rate during this last decade was due to the measures taken to that end, we find that the number of lives saved, representing a total for the decade of 856,804 persons, according to Mr. Farr's estimate

represents a social capital of $650,000,000. Thus in ten years the country has more than regained the sum that was spent in sanitary improvements in the fifteen years, and in this calculation nothing figures for spared grief, better health and happier life. This diminution of mortality is not observed in in all forms of disease. The mortality from zymotic diseases, from 1861 to 1870, was 42.54 per 10,000 living and this was reduced to 24.52 in the period from 1880 to 1889, but measles, diphtheria, whooping-cough appear to have escaped the influence of sanitary measures. Consumption has equally diminished in England in these last years. The mortality from this cause in the years 1861 to 1870 was 24.89 per 10,000 living. For the period 1880 to 1889, it fell to 17.36. The statistics further demonstrate that sanitary measures affect the death rate of young persons between the ages of one and twenty-five years, and especially between ten and twenty years. The gain in this latter decade, which amounts to 28 per cent., is economically a great gain. The death rate for old persons has increased during the last decade, a fact which may be chargeable to the bustle of the nineteenth century, the wear and tear upon the nervous system, while the effect of sanitary improvement is most noticeable in the abatement of infant mortality.—*Amer. Analyst.*

THE INFLUENCE OF WEATHER ON DISEASE.

We may regard it as certain that an apparent connection between infectious diseases and atmospheric conditions had suggested itself to the medical mind long before Sydenham attributed to the atmosphere an "epidemic constitution." The influence of weather would be measured by its effect in providing an environment suitable to germ development. Thus moist weather, whether bleak or warm, would be found conducive to the spread of contagia, and so it is. This fact has often been attested by the extension of cholera, diarrhœa, and the exanthemata. A warm and dry day, on the contrary, tends to check morbid action of an infectious kind. This fact is susceptible of more than one explanation. We may, on the one hand, regard it as a consequence of the absence of that germ fortering condition—humidity; on the other, we cannot fail to be reminded that dry warmth and sunshine give the signal for an exodus from many crowded homes, for their freer ventilation, and consequently for diminution in the intensity of contagia. The exact value of weather changes in regard to this class of diseases, however, still is and must for some time remain *sub judice.* As for the ailments more usually associated with these changes—those for example, more commonly known as inflammatory—the connection is here much more evident, and also in all likelihood more direct. The association of pneumonia, bronchitis, asthma, and rheumatism with bleak and wet weather is too invariable to permit of our doubting its reality apart from any suggestion of septic agency.—*Lancet.*

MEDICAL CHEMISTRY.

LINAMARIN.

MM. Jorissen and Hairs (*Journ. de Phar. d'Anvers*) have obtained from Linum usitatissimum a nitrogenous glucoside, which differs from amygdalin and laurocerasin, and is the source of the hydrocyanic acid which that plant disengages abundantly under certain conditions. Linamarin occurs in the form of colorless and odorless needles, having a very cooling and bitter taste. Is soluble in its weight of water, also in alcohol, but almost insoluble in ether. It is distinguished from amygdalin by several physical and chemical characteristics, which are summed up in the following comparative tables:

AMYGDALIN.	LINAMARIN.
Little soluble in cold water, (1 part in 12).	Very soluble in cold water, (equal parts).
Parts with its water at 120° C. melts and decomposes at 200.	Retains its water at 120° C., melts at 134°, and bears a heat of 150° without decomposing.
Colored purple by strong sulphuric acid.	Not colored by strong sulphuric acid.
Contains 52.51 per cent. of carbon, and 3.06 per cent. of nitrogen.	Contains 47.88 per cent. of carbon, and 5.55 per cent. of nitrogen.
Is reducible by adding an emulsion either of almond oil or of linseed oil.	Reducible by adding a linseed emulsion, but not by one of almond oil.
Benzaldehyde present in reduction products.	No benzaldehyde in reduction products.

ON THE PRESERVATION OF LUNAR CAUSTIC.

M. Bartle, pharmacist of the Vincennes Military Hospital, after an exhaustive study of the matter, concludes that coriander seed, linseed, etc., usually used in the preservation of lunar caustic are more or less deleterious, and recommends in their place powdered or

shredded asbestos that has previously burned, or thoroughly dried, well-dried sand, or, by preference, granulated pumice stone. To obtain the latter it is only necessary to beat the commercial pumice stone in a mortar, and to sift it through a brass sifter in such manner as to get the grains about the size of shot used for bottle cleaning. The fine dust is gotten rid of by sifting in the usual way.

Clippings and News Items.

THE ASSOCIATION OF MILITARY SURGEONS OF THE NATIONAL GUARD OF THE UNITED STATES.

The second annual session of the Association of Military Surgeons of the National Guard of the United States will be held at St. Louis, April 19th, 20th and 21st, 1892. An interesting programme of addresses by prominent surgeons of the National Guard and the United States Army has been arranged, and a goodly number of scientific papers on Military and Accidental Surgery will be read and discussed, and all matters pertaining to the health, usefulness and welfare of the civilian soldiers will receive attention.

COCAINE IN NERVOUS ASTHMA.

Prof. Da Costa recently treated with marked success a case of pure nervous asthma with one-fourth grain of cocaine per diem. After obtaining the desired result the remedy was given only twice afterward, and but once a day.

SALICYLIC ACID AS A DIURETIC.

After a series of investigations on this subject, Huber concludes that salicylic acid is one of the safest and most important diuretics. The greatest increase in the amount of urine seems to occur in rheumatic fever and serious pleurisy, whether the temperature is raised or not. In all cases the total loss of water by the skin and urine was increased, and the solids of the urine were increased. In ordinary pleurisy, and in four cases of cardiac dropsy the drug acted well.

SODIUM SALICYLATE IN RENAL COLIC.

M. Fay, in the *Wiener Med. Blatter*, praises the beneficent action of sodium salicylate in the treatment of nephritic colic. He declares that under its influence the calculi are rapidly eliminated and the patients restored to health. If *true*, this is indeed a boon to suffering humanity, as few tortures are so acute as those of renal colic, and none have hitherto been more rebellious to treatment. Sodium salicylate has also been highly recommended in hepatic colic.

LA GRIPPE.

The "grip"
When you get it
You'll fret it
As it wears you
As it tears you
You'll abuse
While you lose
Your grip;
Not the same,
'Cept in name,
As that other diabolic, pathogenic and prodromic, mucous quirking, top-knot wracking, jointlets cracking, stomach-working, body-burning, brainpan murking, nerves all churning affliction which is called—
Or by æsthetic people bawled
The "influenza" but, for short
When with cold in head you snort
And your temper's on the snip
It's just ordinary "grip."
And its metabolic
Worse than colic
Poison's in your blood
And you wish your name was mud.
Until in sullen fury you let everything just rip—
While in doleful chorus groaning
Your family are moaning
In a sort of runic rhyme
With their vitiated chyme
The solo of the grip.
Not the pip
But the grip, grip, grip
From its talons you can't slip
But must sit and in your person
(For all its woes a curse on)
Exemplify its rule;
And every one's a fool
When the whisky bottle's drip
And the quinine mixed you sip
And pay out pelf
To rid yourself
Of that all-effecting
Naught-delecting
Old world rip,
The grip.

Clinical Lecture.

THE TREATMENT OF TYPHOID FEVER IN CHILDREN.*

BY JULES SIMON, M. D.

PARIS, FRANCE.

Gentlemen :—By a mere coincidence there have just been admitted to our wards, four children suffering from typhoid fever, and I will take the opportunity to study with you the treatment of this disease in children.

Our little patients present different types of the affection. I will here state that the treatment varies somewhat according to the forms of the malady, and that certain typhical conditions require especial management. I will refer to this point later, perhaps at the conclusion of the lecture. In the meantime, I will remark that the treatment of typhoid fever, in my opinion, is subject to certain rules, rules which I will present to you in a synthetical form. In the first place we will examine the forms of the disease in our patients, and then direct our attention to the line of treatment which we shall pursue in each one of them.

The first patient is a boy, 13 years of age, who entered the Hospital on the 15th day of the disease. Up to this time the disorder had followed a regular course, and the patient exhibited a marked eruption of rose-colored spots. According to certain authors these rose-colored spots appear on children with the same regularity as they do in adults, and that the eruption exhibits the same confluent form. Up to the 20th day everything went on regularly with our patient, but at this time there occurred a sudden change; the temperature was considerably lowered, and there appeared what may be called a true urinary crisis, the increased amount of urine being 1500 grammes in twenty-fours hours. In fact, the patient had entered into a condition of convalescence. On the following morning, however, that is on the 21st day of the disease, there came, entirely unforseen, an abundant intestinal hæmorrhage. Intestinal hæmorrhage in typhoid fever in children is of rare occurrence, it being due, I believe, to the fact that in these patients Peyer's patches are not generally hard, infiltrated with lymphatic elements, and that there are no sloughs produced which on being detached give rise to hæmorrhage. In children Peyer's patches are simply exulcerated. Although rare, as I have remarked, intestinal hæmorrhage may appear under two distinct conditions and offer a quite different diagnosis. In certain instances, as in this case, the hæmorrhage is unaccompanied by serious symptoms. The general condition of the child remains good, the frequency of the pulse is comparatively unimportant, and there is no marked elevation of the bodily temperature. Hæmorrhage constitutes, therefore, in these cases, a peculiar kind of crisis. I have seen many examples of this critical hæmorrhagic condition, but I can positively state that I have never observed any serious symptoms develop. On the other hand, when the hæmorrhage is threatening in an individual in whom the temperature is high, the pulse frequent, and in whom there is a general adynamic condition of the system, then hæmorrhage is extremely serious and is generally followed by death. In these cases the hæmorrhage is due to marked alteration of the blood, and may always be considered as a phenomenon of approaching dissolution.

In our patient the hæmorrhage occurred under the most favorable circumstances, and I, therefore, adopted the following treatment: Ice upon the abdomen; two enemata each containing four to five drops of laudanum, to be injected in the twenty-four hours; cooling lemonade drinks; a mixture containing 1 gramme of the tincture of the perchloride of iron. I also advised absolute rest and a diet of cold broths. As I had reason to expect, the results have been most

*Delivered at "Hospital des Enfants-Malades," Paris.

excellent. The convalescence of our young patient has been steady, and to-day (the 28th of the disease) he is doing as well as could be desired. The hæmorrhage stopped three days ago, and he has commenced to partake more or less of a nourishing alimentation. He will be advised to continue the perchloride of iron during the period of convalescence.

The point I wish to impress regarding this particular case is, that the occurrence of hæmorrhage should not be a cause of despair. If the general symptoms are favorable, you must not fear to push the treatment I have indicated, with a right to expect and obtain a happy issue.

The second patient to whom I wish to call your attention, exhibits a type of abortive typhoid fever, in which the symptoms ceased about the 15th day, notwithstanding that the disease is apparently ready to avert or produce at the same time serious troubles. The patient is nine years of age, and entered our service on the 18th day of the disease, with all the typical phenomena of a mild typhoid fever. In this, as in the majority of children, no prodromic symptoms were observed, notwithstanding that the period never fails to appear. This prodromic period, which we have never noticed in this Hospital, will be most frequently met with in your civil practice. In children, it is true, this period of typhoid fever presented phenomena characterized by symptoms of a generally mild nature. The patients show a peevish disposition, suffer from irregular attacks of headache, perhaps one or two during the day. There may be a slight reaction, of a short duration; and, finally, with the appearance of a capricious appetite, there may come on a change in the usual character of the patient. You must be careful, however, in studying the different signs in order to avoid errors; for while you may be assuring the parents of the child of the commencement of a typhoid fever, you may be really dealing with a simple catarrhal affection. Again, you may attribute the symptomatology to an approaching attack of abortive typhoid fever, especially if the general aspect of the patient is not in accord with the rest of the symptoms, particularly with the elevation of temperature. If the general condition of the child is good, and there is an increased bodily heat, the probability is that you are contending with an abortive form of the malady. Apropos of this, I will state that in children the temperature rises easily, sometimes going up as high as 40°C., under the influence of the slighest emotion. It behooves us, therefore, not to suspect the existence of typhoid fever simply on account of the high temperature. You have seen, it is true, in our patient an evening temperature of 40°C., appearing constantly for seven consecutive days, and, nevertheless, convalescence has been established; but at the same time, the pulse, which had been exceedingly frequent, has fallen to 90 *pari passu* with the disappearance of the other symptoms.

Our third patient shows another type of typhoid fever. Not only the usual symptoms have been developed in this case, but, besides, other symptoms of an ataxo-adynamic character have been manifest. In the presence of these nervous symptoms I have thought best to treat the case by the hydrotherapic method. The result of this treatment has been most favorable. At this time I have no longer insisted on the application of baths, although I have always formulated this treatment in general. The child is to-day in a good condition, and convalescence has been completely established.

Our fourth and last patient to-day, is a typical case of typhoid fever, without complications or any anomalous character. In cases like this I advise a general treatment of which I desire to speak to you, a treatment that I invariably employ in regular, uncomplicated cases of typhoid fever in children.

In the first place hygiene must be attended to. As soon as the correct diagnosis is made I order the patient to remove to a new habitation, and a change of bed clothing morning and night. At the same time I order bathing, evening and morning, of the whole body, with aromatized water (thymol or cologne) at a temperature of 30° C. If the bodily temperature is elevated, say to 40° C., I order this bathing to be applied with even more frequency if the heat of the body should show a tendency to increase. This bathing is to be made by means of a sponge, and rapidly, first over the anterior and then over the posterior part of the body, after which the patient should be rapidly wrapped up in order to obtain a slight reaction.

This sponge bathing, I repeat, I am in the habit of employing in every case, and I especially recommend it to be applied frequently in cases of high temperature, and only when there are manifest no serious phenomena of a nervous character. On the contrary, when symptoms of an ataxo-adynamic nature accompany the elevation of

the temperature, then I have recourse to the application of general cold, or better warm baths.

I will not to-day study from a general point of view the question of the employment of cold baths in the treatment of typhoid fever, nor especially how such a measure acts in the case of adults. I will confine my remarks to the consideration of my method of treatment in the case of children and of the results that I have obtained. If, for instance, I observe in a child, at the same time, a high bodily temperature and ataxo-adynamic phenomena, I prescribe from the beginning baths at a temperature of 35° C., of a quarter of an hour duration, progressively diminishing the temperature of the baths to 25° C. The baths are renewed every three hours, but this rule is not absolute, and generally our guide should be the march of the disease, particularly in regard to the amount of fever. The baths then, should be renewed according to the degree of the hyperthermic condition of the patient. This practice which, I assure you, has nothing of a dogmatic character, has given me good results, and you have observed a good example in the case of our third patient. Therefore, to conclude, in children you should always advise the application of cold baths in those cases especially that exhibit ataxo-adynamic symptoms, but abstain from ordering them when there is only a condition of hyperthermia. I will repeat, that a high temperature by itself is of no consequence in the case of children. To this therapeutic measure (generally applied in all cases), you will add an enema, night and morning; if the stools are offensive you will order an injection of borated water slightly aromatized. For drinks, lemonades or some mixture with syrup of orange should be given. The diet should consist, during the febrile period, of broths. You have not heard me speak of milk. The reason is that, according to my experience, milk is not an entirely proper article of food in the typhoid fever of children. With few exceptional cases, milk is badly digested and its administration is followed by a slight exacerbation of fever. Therefore, I prefer to give it during the period of convalescence. In advanced stages of the disease, I prescribe claret, rum, brandy or Malaga.

Such is the hygienic treatment which I apply to typhoid children; but the medicinal treatment is as equally important. If the young patient is laboring under a state of agitation, I prescribe the following mixture:

℞

Hydrate of chloral	gramme 0.50.
Tincture of musk	gtt. xx.
Linden-tree water	grammes lxxx.
Syrup of orange flowers	grammes xx.

This to be administered in dessertspoonful doses in the course of 24 hours.

I prefer chloral to the bromide of potassium on account of the digestive disturbances which the latter remedy is apt to produce. If the child complains of headache, I give small doses of the syrup of codeine; but bear in mind that this is the only opiated preparation which is to be employed in infantile typhoid fever. The extract of quinquina which is frequently used in the enteric fever of adults, ought not to be administered to children. In fact, I will state that the extract produces disorders of digestion and provokes a loss of appetite, especially for those articles of food most advantageous to these young patients.

At the beginning of the 15th day of the disease, I prescribe the perchloride of iron in the following manner: At first, 1 drop every two hours, afterwards double the dose for about two or three days. This remedy can be given in a little water, sweetened or not, after the first mouthfuls of broth. Once taken, the child is allowed to finish his cup of broth. The perchloride of iron is a very valuable remedy in the treatment of infantile typhoid fever. It has given me, in a large number of cases, very good results. The medicament acts not only as a tonic, but it also appears to aid digestion, and thus, it is entitled to its continued administration during the period of convalescence. I insist upon the use of the perchloride of iron, and you will do well in prescribing it also.

I have said nothing so far in regard to the use of quinine. I have purposely left for the last my remarks about this drug. In all cases of infantile typhoid fever you must administer, from the very beginning, the sulphate, and you must continue it during the whole period of the disorder. You will cease its ingestion only when defervesence has been completely established. The doses of the drug will vary according to the age of the patient and the physiological effects produced.—Translated from *Le Bulletin Medical*, Nov. 15th, 1891.

In consequence of the remarkable success claimed in the treatment of drunkenness with hypodermic injections of strychnine, this method of treatment was tried in the city hospital in Görlitz, Silesio, but the results were almost entirely negative.

CHRONIC PELVIC PERITONITIS—LACERATION OF CERVIX WITH RETROVERSION AND PARTIAL PROLAPSE.

BY M. D. MANN, M. D.,

PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY UNIVERSITY OF BUFFALO—ATTENDING GYNÆCOLOGIST TO THE BUFFALO GENERAL HOSPITAL.

Gentlemen:—This woman has come to get an opinion. She is twenty-four, has been married six years, has had no children. She was first unwell when sixteen. She has menstruated at intervals sometimes of four weeks, sometimes of three, sometimes she flows a good deal, sometimes very little. Since she has been married there has been more flowing. It was not painful when it first began but it has been so since marriage. She first began to feel ill five years ago. She had the ague and then scarlet fever during the first year of her married life and she had never quite recovered her strength. She complains of pain in her side. She says she has had a kind of paralytic stroke affecting the left side and even now her left arm is not as strong as it was. The same condition obtains in the left leg and foot. The stroke came on suddenly while she was walking. She did not become unconscious but she could not talk for three or four days. She was almost totally incapacitated for a week or two and for four or five months she was quite weak in the side and could do very little work.

The pain of which she now complains, begins in the left ovarian region and runs through to her back. It is worse when she is unwell and especially just at the conclusion of menstruation. Her period lasts sometimes three or four days, sometimes two weeks. She does no work except about her house, and even that tires her a great deal, and she has to lie down frequently during the day. Her bowels are regular except that sometimes she has to use an injection. The movements are sometimes quite painful.

You hear the history of this case and it is sufficiently common and characteristic. Here is a woman who is in comparatively good health until she gets married. Then she has a sickness in her first year of married life from which she recovers slowly, following this she has what she calls a stroke of paralysis from which she recovers but gradually and partially. About a year ago her health again began to fail. She complains of pain in the ovarian region, backache and general inability to work. What can we say as to the diagnosis of such a case? It might be almost anything. We cannot make a diagnosis although we might imagine what the condition is. Just before I brought her into clinic, I made an examination and I found that on the left side of the pelvis behind the broad ligament, there was a mass of something which did not belong there. I could feel this through the vagina and by examining through the rectum I could feel it very distinctly. Pressure over this mass from the inside caused a great deal of pain and when I made bi-manual palpation she evidently was hurt considerably. There could be but one thing, with this history and with what I find by physical examination to account for her trouble, and that is some pelvic inflammation. It is a little difficult to trace the history of it and to know exactly when it began but probably there was a specific origin for it since the trouble increased greatly soon after marriage and she never has been regular in her menstruation since marriage, and since then she has flowed a good deal more. Probably there was an old gleet existing in the husband at the time of marriage or perhaps a more recent urethritis. It is impossible to tell at this late date just how the trouble originated. However that may be, she has been a great deal worse since the attack a year ago. The pain and suffering referred to the left side has made her a miserable invalid since then. What is the significance of the pelvic mass which I have felt in my examination? It does not mean a pelvic cellulitis, as we used to think, but a pelvic peritonitis having its origin in the Fallopian tube. I cannot tell you its exact cause, but I can tell you its nature. The Fallopian tube is inflamed, prolapsed, knitted together with the ovary into a mass by adhesions and bound to the broad ligament behind. On the other side we can feel little or nothing, and there is no tenderness. At the same time, there may be a less degree of trouble there. The pelvic peritonitis is very apt to be worse on one side than on the other. It is very rare to find one side diseased and the other entirely healthy.

The important question is, what we can do for the patient. She is poor and her husband depends upon her to manage the house. It is exceedingly necessary for her and him that she should have her health and be able to work. It is a question almost between the poor-house and health. What can we

do to help this woman? These cases of pelvic inflammation are very difficult to handle. There is not, in all probability, a pus tube in this instance. The mass that I feel is quite small, very hard, it is not low down in the pelvis and does not give the impression of a large distended tube but of a thickening of tissues and agglutination to other parts by peritonitis. At the same time it causes a great deal of local and reflex pain. There is also intercostal neuralgia which goes so commonly with these troubles, although women often think that the pain is due to heart disease. There is a very close nervous connection between the left ovary and the intercostal nerves, as was pointed out by Fothergill a number of years ago; there is a direct channel for reflex disturbances.

This woman has had a certain amount of treatment but it has done her little good. She has been treated at the Dispensary a year with local applications, douches, iodine, tampons, etc. When she first came she could scarcely walk and for a few months she was benefited, but of late she has made no progress. She probably will not improve further on such treatment. I do not know anything further to do, unless it be to try electricity or perform laparotomy. I have not been satisfied with the use of galvanism in the treatment of these cases. It may be because I do not know how to use it, or it may be because it does not do any good. I have tried it myself and I have seen it tried by those who claim to be experts in its use and without improvement on the part of the patient. A long course of "rest cure" might do this woman some good, but it is absolutely beyond her means. I do not see anything left except a laparotomy and I should expect that by the removal of these diseased organs the patient would be allowed to regain her health. The function of the organs is, of course, destroyed so that the tube could not carry an ovum, but the ovary probably cannot even give off an ovum. The woman would much rather have her health than the exceedingly remote possibility of bearing children. I shall suggest to her an operation, telling her frankly that I do not know anything else that will cure her. The risk of laparotomy is comparatively slight and the chances of good results very great.

Pyoktanin, though no better, perhaps, than corrosive chloride or some other articles to prevent wounds becoming septic, is, however, much better to disinfect a wound which has become septic or infected.

Communications.

THE IMPORTANCE OF BLOOD CLOT IN TREATING DEAD SPACES.*

BY MONT. LINVILLE, M. D.,
NEW CASTLE, PA.

Since the days of Ambrose Paré the progress of surgery has been steadily onward and upward. History is full of illustrious names; but in the years to come the name of Lister will stand out more prominent than all others. In teaching us the importance of cleanliness and the use of antiseptics and the drainage tube, he has not only conferred the greatest boon on suffering humanity, but gave medical men of the present day an impetus to learn how to assist nature in healing wounds without interfering with her laws.

In olden times the blood was considered the plastic material which filled the holes like the glue and cement which stick together the edges of a wound, but now we fear the most dangerous results from its decomposition, and use our best efforts to keep a wound free from it, and the surgeon who fails to check hæmorrhage will look in vain for successful results from his antiseptic technique. But when we change our views on any question, the pendulum of thought often swings too far in the opposite direction. May we not have fallen into the same error on this subject.

For more than twenty years the eyes of every thinking surgeon have been turned towards the great Lister, who has never lost an opportunity to emphasize wound drainage, and he is still untiring in his efforts to discover the best means for so doing. But during the last eight years other great minds have proposed methods for healing wounds without drainage tubes. Seven years ago Neuber contributed an interesting article on this subject. He recommended irrigation with a sterilized solution of salt, and drainage by loose stitching. To get rid of dead spaces he advised buried sutures inverted stitches, flap implantations and compression from without, but this plan is not only tedious, but often impossible to thoroughly obliterate the dead spaces in wounds.

I have worked until I was nearly exhausted in trying to carry out this plan of

*Read before the Association of the Surgeons of the Pennsylvania Railroad Company in Chicago, Oct. 20th, 1891.

treatment, but I do not believe that I ever thoroughly succeeded in obliterating the dead spaces. More than once in such cases I have been surprised and gratified to find that the wounds healed by the first intention just as regularly as the most simple wound without dead spaces.

Recently my mind has conceived the idea that there is something in Schede's theory of wounds healing under the moist blood scab.

He says, "It has required only a moderate experience with antiseptic surgery to enable us to recognize that even large blood clots in open wounds do not necessarily undergo destruction or decomposition, that they do not necessarily give rise to inflammation and accidental diseases, but that they take on changes which we may designate as organization of the blood clot, and which one may compare with the conversion of the thrombus in ligated blood vessels." This calls to my mind the words of the immortal John Hunter, which I first heard when a student from the lips of that grand old man Professor Gross: "In many deep-seated wounds where all the parts have remained in contact, those underneath will unite much better if the surface be allowed to scab. Compound fractures [more especially where the external wound is small] should be allowed to heal in the same way; for by preventing the blood to scab upon the wound either by itself or when soaked in lint, the parts underneath will unite, the blood under the scab becomes vacular, and the union will be complete even when the parts are not in contact. Many wounds ought to be allowed to scab in which this process is now prevented; and this arises, I believe, from the conceit of surgeons who think themselves possessed of powers superior to nature, and therefore have introduced the practice of making sores of all wounds."

Gentlemen, the author of these words was certainly far in advance of his time. I am aware that I stand on debatable ground, and that many may assail my position, but I only claim to be an humble learner, and if I can provoke a discussion on the few points which I may be able to hint at in this short paper, perhaps I may be able to absorb some practical knowledge that will pay me for my long journey to this meeting.

I honestly believe that the blood clot is the important factor in healing many wounds where we have dead spaces. And that too many surgeons do harm by trying to get rid of it, by the use of drainage tubes, and the application of strong antiseptic solutions.

Do not understand me to say that I am opposed to antiseptics or the use of drainage tubes. I believe that it is our first and most important duty, to thoroughly antisepticize our hands and the external portion of the wound, but we meet with many cases where the wound is deep, with large dead spaces, that I believe the use of carbolic acid or corrosive sublimate destroys the physical and, perhaps, the chemical characters of the blood, and produces a superficial necrosis which must retard healing. In operations upon diseased bones, where it is impossible to remove every particle of diseased bone or tissue, and where a profuse discharge is sure to follow, I am in favor of drainage, but in all wounds where the cavity is composed of healthy tissue, I believe that nature is superior to a drainage tube. In amputations if we cut our flaps short and neat, stitch the muscles and close the flaps by buried skin sutures there is no reason why we should not have rapid healing by first intention. I will very briefly relate the history of a few cases which I have treated during the last three years.

Case I.—Miss W., age 55, consulted me last September for carcinoma of right mammary gland; the tumor extended across the sternum and the axillary glands were involved. I found it necessary to remove the breast, pectoralis fascia, a large portion of the pectoralis major, the glands and adipose tissue in axilla, and skin fascia and muscles down to the sternum and ribs, three inches wide and five inches in length, this portion of the wound was without a covering, and presented a frightful appearance, I permitted the wound to fill with a blood clot, after which it was dressed antiseptically. I did not open it for a week, when I found the blood clot organized and a healthy scab covering the entire wound, which was completely healed in twenty-eight days. The patient has gained twenty pounds and thus far there is no sign of a return of the disease.

Let me digress for a moment, while I say that experience teaches me that the only hope of permanent cure in carcinoma of the mammary gland is not only to remove the entire gland but the axillary glands and a liberal portion of the surrounding tissue. Even the pectoralis major muscle nearly up to its insertion into the arm.

Case II.—Railroad brakeman injured while coupling cars. There was a compound comminuted fracture of the right arm, involving the elbow joint, which felt like a sack of small bones; the skin was broken

through in five places; there had been profuse hæmorrhage but was checked, or nearly so, by blood clots when I saw the patient. The arterial circulation being good I decided to make an effort to save the arm. I enlarged the wounds sufficient to remove lacerated pieces of muscles, and fragments of the humerus, olecranon and condyles of elbow joint. I then placed the arm in a solution of corrosive sublimate one to one thousand for several minutes; by this time the clots which had been broken up were reformed. No stitches were used, the arm after being dressed with iodoform gauze and loose bandage was placed on a straight splint. I redressed it in five days and found the blood clots red and healthy, and that they would bleed if gently touched with a probe. In four weeks the wounds were healed, and although the arm is weakened he has good motion in the joint.

Case III.—A German merchant, who was an excessive beer drinker, consulted me four years ago on account of a running sore on the anterior portion of right leg. I found that the anterior portion of tibia was diseased about three inches in length, also the soft parts for a much larger circumference. I removed every particle of diseased bone and tissue with a curette, and allowed the cavity to fill with a clot. I then applied the usual dressing, and on the fourth day found the clot was organized and healthy; this case gradually progressed to complete recovery. The cavity was filled so as to make the limb smooth and natural.

If time permitted I could relate several cases of compound fracture of the leg where there was not only loss of bone, but of the soft parts over the seat of the fracture, in which nature repaired the injury by organized blood-clot.

The dressing of this class of wounds is an important matter; gutta-percha tissue is an excellent protection, and enables the surgeon to avoid injuring or tearing away the scab during subsequent dressings. The old habit of dressing wounds every day or two, and each time tearing the wound open by so doing, was barbarous and I often wonder that nature did not rebell with such emphasis as more frequently to prevent recovery.

The less we disturb a wound the better; in all favorable cases of amputations one or two dressings should be sufficient. In the past much harm has been done, and many limbs and even lives have been sacrificed by tight bandaging. I am glad that this matter is being constantly agitated. We always know better, but it is so easy to overdo it that we constantly need to be reminded of the danger.

The buried suture in many cases is a great improvement. How often have we found the holes in the skin produced by the stitches full of matter, and the wound healed by first intention. The skin, no matter how thoroughly disinfected, may contain the germs for producing septic trouble, but the cavity of a wound if in a normal condition may be capable of disposing of large quantities of micro-organisms.

A frequent cause of suppuration in infected wounds is obstructed circulation, and nothing is so liable to cause it as tight ligatures and sutures. Experience teaches me that I have committed more than one sin against nature in this way during the early years of my practice. Methinks it a good plan to use weak silk, and if we occasionally break it we are reminded that we are using too much force.

I hint at these small matters, because they all belong to the one great family in wound treatment, and it will not do to neglect the most minute detail if we wish for reasonable success.

We may be successful in treating wounds with dead spaces, either by obliteration, drainage or blood clot, providing we thoroughly disinfect the skin and everything that touches the patient.

In conclusion let me say that while I do not recommend dispensing entirely with the drainage tube, there is a strong tendency in that direction among some of the bright surgeons of to-day. We love to boast that surgery is a true science, but we never should forget that nature is the great physician, and that the best we can do, is to assist her in the simplest manner possible.

The blood clot theory is not new. It is being tried here and there by progressive men who are loud in its praise. We live in the age of rapid thought, and the physician who loves the profession, and works for something more valuable than money, must be devoted to hard study and extensive reading.

The multiplicity of ideas requires him to have a clear brain and quick judgment if he wishes to stand somewhere near the front rank, and to be a blessing to suffering humanity. I am reminded of the lines often quoted by the August Nestor:

> "A wise physician our wounds to heal,
> Is more than armys to the public weal."

And again those quoted by Paulus from that grand old poet Homer:

"The man of medicine can in worth with many warriors vie,
Who knows the weapons to excise, and soothing salves apply."

A CASE OF THERMIC FEVER COMPLICATED BY CROUPOUS PNEUMONIA.

BY CHARLES B. WILLIAMS, M. D.,
RESIDENT PHYSICIAN, PENNSYLVANIA HOSPITAL, PHILADELPHIA.

John P. L., age 27, white, a vigorous, healthy looking man, employed at Spreckles' sugar refinery, having been overcome by the heat was brought to the Pennsylvania Hospital by the police patrol on June 17, 1891, during the service of Dr. Morris J. Lewis. On admission at 2.35 P. M. his temperature per rectum was 110°; pulse 160; resp. 42. He was intensely cyanosed about the face only. The rest of his body was burning hot to the touch. His eyes were markedly congested—the pupils were contracted and the eyeballs were rolled upwards. He was in a state of profound unconsciousness.

His breathing was rapid, stertorous and labored and accompanied with a loud rattling in his throat. His bowels were moving involuntarily when he was brought in and moved continuously for 20 minutes after admission. He had had convulsions before admission but none after. His pulse was scarcely perceptible at the wrists. It could be counted at the carotids and by the stethoscope. There was a profuse, frothy, mucous discharge from his nostrils.

At 2.35 P. M. he was given an iced enema and an hypodermic of tr. digitalis ♏x with whiskey ♏xv. His bowels continued to move for some time after the iced enema had been given. At 2.55 P. M. his temperature had fallen to 103⅗°; pulse 160; resp. 52. He was given another hypodermic of digitalis and whiskey. At 3.10 P. M. his temp. and pulse were the same but his respirations were 40 per minute. He was now given an hypodermic of strychniæ sulph. gr. $\frac{1}{60}$. At 3.20 P. M. the first sign of reaction occurred. His temp. was 102⅖°; pulse. 136; resp. 32. It was now that the ice rubbing produced a marked redness over his body surface, and the spraying from the hose would cause him to writhe and twist about; for previous to this, while the ice and hose were being applied he had remained quite immovable. Between 3.20 and 3.35 P. M. the hose was again applied. His temp. at 3.35 P. M. was 102½°; pulse 124; resp. 34. The hose was now applied for the last time between 3.35 and 3.50 P. M. At 3.50 P. M. his temp. had fallen to 100⅗°; pulse 110; resp. 28. He was now thoroughly dried and placed upon another bed. At 4.05 P. M. his temperature was 99°; pulse 120; resp. 32. He seemed very restless and was writhing and twisting about the bed a great deal. He was accordingly given an hypodermic of morphiæ gr. ¼ et atropiæ gr. $\frac{1}{100}$. At 4.20 P. M. temp. was 98⅘°; pulse 132; resp. 32. At 5 P. M. his pulse still continued to be very rapid and feeble. Ordered another hypodermic of tr. digitalis ♏x and whiskey ♏xv. At 5.20 P. M. his temp. arose to 104°; pulse 120; resp. 32. Had another hypodermic of digitalis and whiskey. At 5.45 P. M. his pulse still remained unchanged. Ordered him hypodermics of whiskey every fifteen minutes until 8.30 P. M. From 6 P. M. until 8.30 P. M. he seemed very restless and twitchy and he was therefore given another hypodermic of morphiæ gr. $\frac{1}{8}$. During this time he also received two more hypodermics of tr. digitalis and whiskey. His pulse could now be distinctly felt at the radials.

As he still continued very restless, his wrists and ankles were strapped to the bed. When the patient was removed to the ward at 8.30 P. M. he was still in an unconscious condition. He was ordered to have an ice cap to his head and hypodermics of whiskey every half hour until 11 P. M. After which time he had them hourly with spts. ammon. aromat. f ʒss. by mouth. The patient slept through most of the night and awakened in the morning and desired to know where he was—how he had come to be in the Hospital and why the straps were on his wrists and ankles. Temperature was now 99⅘°; pulse 98; respiration 18. His pulse was rather feeble and although his general condition was remarkably improved yet he seemed rather dull and slept a good deal. His urine examination now showed a specific gravity of 1022—was clear, yellow, acid and contained albumen. Microscopical examination showed numerous hyaline and epithelial with pale granular casts.

On the following day, 19th, he seemed muddled and dull of comprehension and when asked a question he would reply in such a manner as almost to indicate that he had been having a little too much spiritus frumenti. His pulse was 84 and of fair volume, and respiration 28. His stimulus and digitalis were immediately discontinued and

he was given sodii brom. gr. xv. t. d. and also calomel gr. ½ et sodii bicarb. gr. v. q s. h. The following note was made on this day: There is no left knee-jerk and none on reinforcement. His feet have a curious mottled appearance. He has good power and grip in both hands. His face draws up more on the right side than on the left. His tongue comes out straight, but possibly it turns a trifle towards the left. There is no difence to be seen in the movement of his forehead. He can read understandingly, and speaks in a thick voice as if he had something in his mouth. Right pupil is a trifle larger than the left. Pupils react to light and accommodation. He has a slight elbow jerk. On June 21st he became delirious and continued so more or less until the end of the month. He had numerous delusions and hallucinations and could not be reasoned out of them. His temperature during this time ranged between 99°+ in the morning to 102–3 and 4+ in the evening. On the 27th he began coughing a good deal. His sputum was profuse, greenish, muco-purulent and tenacious. On July 1st physical examination of his chest showed that fremitus was most marked over his right chest anterior. Percussion note good and very resonant; expiration over right chest was rather prolonged with a few cooing rales. Posterior—right base, percussion note is flat, tubular breathing, ægophony and sub-crepitant rales. Three days later the following note was made: Percussion note is still flat over the right lung posterior, tubular breathing and sub-crepitant rales can be heard in the right spinal gutter. Of late his temperature has been keeping close to the normal in the day time with an evening rise to 103° or 104°. + His temperature usually begins to rise from 6 P. M. to 11 P. M., when it reaches the maximum 104°. Antikamnia in repeated doses of gr. jss and gr. iij seemed to have no effect in controlling this rise of temperature. The same could be said of antipyrin and quinine. The latter drug having been administered as high as gr. xxxvi. per diem. Urine examination made on July 10th, showed a specific gravity of 1018, was clear, yellow, slightly acid, albumen and casts negative, some triple phosphates.

In addition to the above drugs the patient was receiving ammon. carb. gr. v. every four hours besides milk punch t. d.

On July 18th the following note was made: Chest—There is good movement anterior and but slight impairment in resonance at the right apex. A few moist râles can be heard posterior on the right side and mostly at the root of the lung. He perspires profusely at night and especially after the small doses of antikamnia.

On the 16th of August his chest seemed to be perfectly clear, and his temperature has been keeping within the limits of 101⅘°. The attack of croupous pneumonia caused the patient to emaciate rapidly but after his chest began to clear up and his cough had ceased he soon commenced to regain his strength and weight.

On September 4th, his temperature reached normal and showed no inclination to rise after that time—his cough had ceased entirely and he seemed to be in perfect health. He was discharged cured, on September 19th, 1891.

The patient's temperature chart is a curiosity. It is 8 feet 2 inches in length and its record covers a period of three months with the exception of two days. In all of this time the patient's temperature never reached the normal to stay any length of time until a few days before his discharge, when it showed no inclination to rise again and he left the Hospital—a picture of health. At the present time the patient is doing well and he has no return of bad symptoms.

FRACTURES AND INJURIES OF THE SPINE IN THE CERVICAL REGION—FRACTURE OF THE THIRD VERTEBRA—CERVICAL SPINAL HÆMORRHAGE, FRACTURE OF ODONTOID, FRACTURE OF FOURTH VERTEBRA.*

BY DE FOREST WILLARD, M. D.,

SURGEON PRESBYTERIAN HOSPITAL; CLINICAL PROFESSOR ORTHOPEDIC SURGERY UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

The following group of injuries to the spine, taken in connection with the cases of laminectomy reported by me in the *Transactions of the College of Physicians*, Philadelphia, January, 1890, and February, 1891, show that the prognosis in the majority of the cases of injury to the spine is determined almost entirely by the initial lesions—*i. e.*, the amount of injury which has been primarily inflicted upon the cord. In nearly all cases of spinal fracture the substance of the cord receives severe contusions or lacerations, and the resultant symptoms are not only dangerous, but it frequently happens that death ensues in a short time.

*Read before the Philadelphia County Medical Society, December 9th, 1891.

The first case shows that even very positive bone injury in the cervical region may produce symptoms of but moderate severity, provided the cord be uninjured.

Fracture of Third Cervical Vertebra.—E. R., male, aged thirteen years, fell through an elevator shaft some thirty feet. He was picked up unconscious and removed to the Hospital. Upon examination a large hæmatoma was discovered over the occiput, but there were no external evidences of injury. The head was retracted and turned markedly backward; it could be bent only slightly from side to side. Rotation was possible only to a slight degree. A finger passed into the mouth discovered a distinct prominence behind the posterior wall of the pharynx corresponding to the third cervical vertebra. The rigidity of the neck muscles was great. There was no paralysis, no cough, no loss of sensation, nor could crepitus be discovered. There was no evidences of severe pressure upon the cord. Flexion, extension, and rotation were almost impossible.

Under strong extension and counter-extension applied upward from the head and downward from the body the deformity was markedly reduced. A plaster-of-Paris collar applied while extension was maintained was accurately fitted, so as to keep the head in a fixed position. This bandage was arranged so as to press on the occiput as high as the prominence, also to press upon the mastoid and temporal bones, and to curve forward so as to encircle the lower jaw. It then accurately fitted the neck from whence it extended to the shoulders and passed down loosely to envelop the upper part of the thorax. This maintained the head accurately in position and prevented any movement of the upper portion of the trunk, neck, or head. This was applied in place of extension and counter-extension on account of the sensitive condition of the hæmatoma over the occiput. After the tenderness from the blood tumor had disappeared, weight and pulley extension were applied to the head and feet up to the point of comfortable endurance. The plaster envelopment was sawn open and permitted to remain as a splint to prevent lateral rotation and flexion.

He was kept in this position for six weeks. There was no impairment of motion or sensation during this time. The extension apparatus was then removed and an accurately fitted neck splint of plaster-of-Paris was applied. He wore this with comfort six weeks longer. At the end of this time examination of the pharynx showed that while there was still a slight prominence in the posterior part of his throat, the deformity was much less evident than at the time of the injury. There was still less rigidity, but no deviation of the vertebral column could be discovered. The absence of pressure-symptoms resulting from the injury was a point of special interest. A year later he could move his head in all directions, although motion of the chin to the right was limited. Flexion seemed perfect. It is but seldom that a patient either breaks or dislocates his neck without more serious symptoms.

Cervical Spinal Hœmorrhage.—W. M., aged eighteen years, was injured by diving eighteen feet into a pool of water two feet deep. He struck his head and the back of his head on the bottom of the pool. He was immediately pulled out by his comrades and was found to be unconscious. He remained in this state two hours. When first seen, some time after, he was blanched and pale, and complained of a pain in the back of his neck and beneath the shoulders. Sensibility was present throughout body and legs but apparently diminished. There was no opisthotonos, and no rigidity of the neck other than that motion gave slight pain. There was no tenderness over the region of the spinal cord, except slight pain in the lower cervical region. There was no visible displacement of the vertebræ, and no positive evidence of dislocation or of fracture. Flexion, extension, and rotation of the head were perfect and accompanied with only slight pain. The spinal column could be flexed and extended normally. Motion and extension in both arms, body, and legs seemed in good condition, except as regards sensibility as above noted.

He was partially conscious and could answer questions intelligibly, but with an apparent effort of the will, and his speech was slow. There was anæsthesia of both hands, especially on the ulnar side. He complained of pain in the region indicated. There was constant and decided priapism.

This condition continued until about seven hours after the accident, when he slowly seemed to lose power of the hands and forearms on both sides, commencing apparently in the region supplied by the ulnar nerve. Also there was progressive loss of sensation in both hands and forearms. Both brachial plexuses were sensitive to the touch, but not painful. Priaprism still continued, but the urine was voided naturally. The scrotum was anæsthetic and remained so for several days, and uncertain areas of the abdomen

seemed in the same condition, but his answers to questions were not very satisfactory. The legs retained both motion and sensation although both functions were apparently diminished.

The patient seemed to rouse from his unconsciousness at the end of the first hour and was moderately intelligent.

Up to this time extension made upon the spinal column by means of the head gave relief from pain, therefore, an extension and counter-extension apparatus was applied to the head and extremities, and continued traction was maintained.

Loss of motion and sensation increased during the next twenty-four hours until the patient was able only to move his arms feebly; fingers immovable. Sensation was entirely absent in both hands in the region supplied by the ulnar nerve. Sensation was impaired in other regions of the forearm and hands.

During the next two days there was apparently no change either as regards motion or sensation, but on the following day both functions began slowly to return.

At the end of the fifth day he could raise his arms, but only for a moment. When the extensor muscles were required to fulfill their functions the arm immediately fell. There was still a tendency to priapism, but the condition was not constant, the scrotum was still anæsthetic. Temperature, pulse, and respiration remained unaltered.

Continuous extension was maintained, and as there was no paralysis it was deemed probable that all hæmorrhage within the canal had ceased.

Motion and sensation returned to a slight degree in the thumb and fingers of the hand and in the arm, until gradually both functions were restored almost entirely. The scrotum remained anæsthetic for ten days.

Fifteen days later he could grasp an object with considerable firmness.

A trapeze was rigged over the bed so as to exercise the arms while extension was being maintained. An ischio-rectal abscess discharged for two weeks and then healed.

In eight weeks had thoroughly recovered and presented no abnormal symptoms. Motion and sensation complete.

A peculiar condition regarding this case was that after the condition of shock had passed away there was no serious symptoms until the probable occurrence of hæmorrhage had begun to make pressure upon the spinal cord and thus to interfere with its functions. The occurrence of paralysis upon both sides instead of upon one, and the length of time after the injury showed that the symptoms must have been largely due to gradual compression.

Fracture of the Odontoid Process of Axis with Dislocation of Atlas.—C., aged 18 years, fell 20 feet, striking upon his head. He was picked up stunned, but soon regained consciousness. He was able to walk to his home, several blocks distant, and to talk with his friends. An hour and a half later he was perfectly rational, talked freely and pleasantly, and complained of no pain when at rest; he simply desired to be permitted to sleep. He was quiet, but would suddenly start with an anxious look. The trunk and extremities were cold; pulse 85, feeble. Pupils equal, but failed to respond readily to light. The head was thrown backward with the occiput to the right, but he complained of no pain. The chin protruded, and the thyroid gland was prominent. Any movement or rotation of the head toward the right was accompanied with pain. Motion to the left was painless for a quarter of a circle, but any greater motion caused discomfort. There was no contusion or laceration of any part of the body; no depression of the skull, nor any evidences of fracture of the cranium. Pressure over the cervical region gave severe pain. The spinous processes of the cervical vertebræ were in line up to the third, but above this was a marked depression, while a little higher the position of the atlas was slightly projecting to the right of the median line. Manipulation caused so much pain that ocular examination of the pharynx could not be made. Digital examination revealed a slight prominence of the second vertebral body.

Diagnosis.—Dislocation of the axis from the atlas; probable fracture of odontoid.

During the night he slept at intervals, but roused at the slightest noise. There was no pain, except upon the movement of the head.

In the morning he took nourishment, and complained of no suffering. He ate a light breakfast, and was anxious to go to his business. Three hours later he began to grow drowsy, and in two hours became semi-unconscious, but could still be roused. He answered questions intelligently, but closed his eyes as soon as he had ceased speaking. The tongue was protruded straight from the mouth, and with difficulty; the pupils responded to light; the right eye was a little more responsive than the left. There was no paralysis, except of the bladder, the urine not having been passed since the acci-

dent. The catheter secured eight ounces of apparently normal urine. Pulse was 80, full; respiration 16, deep but not snoring.

Twenty hours after the injury the pulse was 48; respiration 12, somewhat stertorous, not puffy nor blowing. Could be roused only with effort. Answered unintelligibly; occasionally, however, an articular word escaped. He constantly pulled at the bedclothes. The urine dribbled. Pupils were nearly the same size, but the left responded more readily to the light. At the junction of the forehead with the hair, for an inch and a half to the left of the media line, apparently the point where the head came in contact with the ground in the fall, the scalp was œdematous and there was a slight depression. Pressure upon several points in the same region gave similar pitting. No evidence of fracture.

No injury could be discovered in any portion of the body save the neck.

There was no paralysis of any portion of the body, but there was slight impairment of motion of the right arm and leg. The head could be moved with little more freedom toward the left, but a slight force caused the patient to cry out and to steady his head with his left hand. There was rather less deformity than at first at the back of the neck; the thyroid was not so prominent. Liquid food was taken without difficulty. He passed a restless night, constantly pulling at the bedclothes, tossing about on his couch, and muttering in delirium.

Forty hours after the injury it was noticed that he moved the right arm and leg less frequently although both members could still be brought into use by a special effort of will. Pupils as the day before; respiration also; pulse 60. The patient responded to loud shouting, but could give no intelligible answers, although frequent attempts at utterance were made. The urine dribbled constantly.

Seventy-two hours after the accident the pulse was 100; respiration 20. Increased loss of power, but members still capable of being moved.

Eighty-four hours after the injury the pulse was 130, feeble; respiration 24. Delirium less violent. Patient remained quiet, except when partially awakened. When roused by any cause the left hand still pulled the bedclothes. The right arm and leg were still capable of being moved slightly, but the muscular power was weakened. Unconsciousness increased with total inability to speak. Bowels not moved since the accident. Pupils normal in size, still contracting under the influence of light. Liquid nourishment has been swallowed up to this time, but was now refused. Died quietly ninety-eight hours after the injury.

Post-mortem.—Examination of the neck alone was permitted. The posterior cervical muscles were filled with extravasated blood from the occiput to the fourth vertebra. The spinous prominence of the atlas lay to the right of that of the axis and on a plane posterior to it, causing the axis to appear as though it had been pushed forward. In reality, however, its position in relation to the third vertebra was normal—the atlas being the dislocated bone. The left inferior articular process lay behind the articular process of the axis, while the right inferior articular process of the atlas lay anteriorly. This displacement was permitted by a fracture of the odontoid process of the axis. One fracture extended directly across its base, while the other had broken off a small portion of the anterior surface—the line of the fracture being almost at right angles to the first. The odontoid process, however, was still held in position by the transverse odontoid ligature, which was unruptured. As noticed during life, the atlas could not be rotated to the right, while it could be turned to the left. Strong extension made upon the atlas permitted it with difficulty to be brought into position.

Fracture of the Third, Fourth, and Fifth Laminæ; Death.—W. P., aged forty years, fell from a scaffolding, a distance of twenty feet, striking the top of his head on a curb, and alighting as nearly as possible with the axis of his body in a straight line. When seen half an hour later he was suffering from shock. His pulse was 80, and his respiration feeble. He was perfectly conscious but indifferent to surroundings. There was a large, lacerated wound of the scalp four inches in length transversely across the forehead. In the region of the third and fourth vertebræ there was marked displacement forward of the third with prominence backward of the fourth dorsal spine. There was total paralysis of both motion and sensation, and of all parts of the body below the portion supplied by the corresponding nerves. Neither urine nor fæces had been passed since the accident. There was no priapism. Extension and counter-extension had no effect on the deformity.

The patient rallied for two hours, the pulse reaching 110 and the temperature 100°. He complained a great deal of pain in the back of his neck and shoulders. Soon

afterward the respiration became more hurried, the heart's action much more feeble, and although perfectly conscious for one or two hours, he soon sank into a state of drowsiness, and died ten hours later.

At the autopsy there was found a fracture of the body of the fourth dorsal, with fracture of the laminæ of the third, fourth, and fifth. The third was greatly displaced forward, carrying with it a fragment of the fourth. The cord was entirely torn across at the junction of the third with the fourth, and was pulpified for half an inch and compressed by the fragments of the other laminæ.

Laminæctomy would have relieved pressure, but would not have restored the crushed and torn cord.

SUPRA-VAGINAL HYSTERECTOMY.*

BY J. M. BALDY, M. D.,

PROFESSOR OF GYNÆCOLOGY IN THE PHILADELPHIA POLYCLINIC; SURGEON TO GYNECEAN HOSPITAL; GYNÆCOLOGIST TO ST. AGNES' HOSPITAL.

It is not the object of this paper to discuss the different methods of surgical treatment for uterine tumors nor to more than incidentally touch upon their medicinal treatment. My personal practical experience in the surgical direction has been wholly that of supra-vaginal amputation, excepting in those cases of small uterine fibroids where it has been been found advisable to remove the appendages only. In this connection I may say that where the opportunity presents to choose between the removal of the appendages and the enlarged uterus itself, I always favor the removal of the diseased uterus, along with the tubes and ovaries. The one and only point which comes into consideration in this decision is whether or not the uterus is large enough to be delivered through the abdominal incision. If it can be delivered, the hysterectomy is always performed. To my mind one of the great advantages gained in hysterectomy, by the extra-peritoneal method, over oöphorectomy, is that no stump or raw surface is left in the peritoneal cavity to become the seat of suppuration, or to whose freshened surface loops of intestine can become adherent. In uncomplicated cases the operation amounts to little more than an exploratory incision, and in my opinion is as safe as an ovariotomy.

I have operated fifteen times for large uterine tumors. In fourteen cases the uterus was removed, but in the remaining case the operation was ended as an exploration. Of the fourteen finished operations, two died.

The patient whose tumor was not removed was a white woman about thirty-five years of age. The growth had existed for more than ten years. When she was first seen she was in bed, where she had been for some weeks, with an attack of abdominal pain. For months she had only been able to be about at odd times, and considered her life a burden. An operation had been proposed to her a long time before, and its dangers brought vividly before her eyes. She had continued to suffer from pain and hæmorrhage, until, in spite of her former fears, she was, at the time I saw her, determined to have the operation performed at all hazards. In spite of her long suffering she was still a strong, hearty-looking woman. The abdomen was opened at the Gynecean Hospital before a number of physicians, and the tumor found to extend above the pelvic brim. The intestines were adherent over it at various points, and had to be torn loose in order that a careful exploration could be made. The growth was found to be in the broad ligament, and was consequently immovable. The only adhesions which existed were the intestinal ones, which had been torn through. The removal of the tumor meant a complete enucleation of a solid growth, with all the chances of death from hæmorrhage which such procedure entails. It was decided wise to end the operation, explain the condition to the woman, and let her decide whether or not she desired to risk its removal at some subsequent time, or preferred a trial at electro-puncture. The result was a complete symptomatic cure. It is now some five or six months since the operation and the woman declares she has never been so well in her life; she attends to all her duties, goes to dances, and in other ways leads an active life. She declares that the tumor is rapidly decreasing in size, and is most confident that it will disappear altogether. She looked at me most sceptically when I told her it would not go away, and that some day all her old symptoms would come back.

The last time I saw her—a month ago—I was considerably staggered by the fact that there was an undoubted decrease in the size of the enlargement. It is barely possible that it might eventually turn out to be

*Read before the Philadelphia County Medical Society, December 9th, 1891.

another example of a solid tumor becoming absorbed after an exploration; several such cases have been reported by Tait and others.

One of the points of greatest interest to me in this case is the fact that her relief is not dissimilar to what is claimed for the electrical treatment. Had she gone to Dr. Massey for that treatment, as I advised her to do, and which she would have done had she not gotten well so rapidly, electricity would have obtained the credit for the cure. As it is, the lesson taught should not be lost. Is it not possible that the great relief apparently obtained by the electrical treatment is at times a mere coincidence? Or would not any profound impression bring about a similar result in at least some of these cases?

The two cases which died were both very bad subjects for operation, and their deaths can in no way be used as an argument against the operation. The true deduction to be drawn from the result in these two cases is that the operation should not be left as a last resort, as is advocated by Keith and the electricians, but that it should be undertaken early, and while the tumor and patient are both in a good condition of health. It is the same old battle which had to be waged so long and so vigorously in the case of ovarian cysts, and the end will be just as surely the same—that is, removal before the woman's health is broken down, and before the tumor becomes unhealthy and adherent.

The first death occurred in a colored woman, about 35 years of age. The tumor was extremely irregular, and extended up to the ensiform cartilage. The patient was in the last stages of emaciation, and could only walk with the greatest difficulty. It was a serious question in the minds of some of my colleagues, who examined her, whether the disease was not splenic or a malignant omentum. I was rather inclined to the latter opinion myself, and went to the operating table prepared to meet any condition or complication whatever. The woman, her husband, and her doctor were all told that her chances for recovery without the operation were *nil;* with the operation that they were little better, although there were some and the only chance. They all agreed upon having the operation, and it was performed at the Polyclinic Hospital in the presence of my class. The omentum was adherent over the upper part of the tumor, which proved to be a nodular uterine fibroid. The omental vessels, which were as large as the radial, were tied and cut away, and the tumor delivered. The appendanges were diseased, and on one side the tube was distended with caseous matter. A good pedicle was secured, and the woman was in her bed within the hour. For five and a half days there was but a single bad symptom—a pulse between forty and fifty beats to the minute. The bowels were opening daily of their own accord, the temperature was normal, the appetite was good, and solid food was being taken with a relish. The abdomen was flat, and there was a minimum amount of pain. She was so well that her doctor was notified that she was safe. At the end of the fifth day she began to develop bad symptoms; the abdomen gradually distended, the pulse became rapid and hard, the temperature slightly elevated, the bowels obstinately constipated, food was refused, and finally vomiting set in, and she died at the end of three and a half days from septic peritonitis.

How it was contracted is still a mystery to me, as there was no drainage-tube used, and the dressings had not been touched since the day of the operation. The stump was perfectly dry and sweet.

The second case was that of a white woman, thirty-two years old. Three years ago she had consulted me, and refused operation, preferring electrical treatment. Off and on during this period she was under the care of Dr. Massey, and toward the end he resorted to electro-puncture through the vaginal vault. She stood this treatment fairly well for a few times, but finally suppuration occurred and a sinus track opened on the outside of the left labia. Pus discharged freely from both the vagina and the outside sinus. When Dr. Massey asked me to see her with the view to an operation, she was bed-fast and could barely move; she was profoundly septic, and too tender to handle. A finger in the vagina disclosed a fluctuating nodule, apparently of the fibroid, in the posterior cul-de-sac. This, taken in conjunction with the discharge of pus, made a pretty clear diagnosis of suppurating fibroid tumor following electro-puncture. I gave as my opinion that the only chance the woman had for her life was to get rid of the suppurating mass. Everybody concerned was willing and anxious that she should be given the chance, so I admitted her to my wards at St. Agnes's Hospital and performed the operation. The intestines and omentum were found adherent to the top of the tumor; the tumor was adherent in every direction to the pelvic walls; both ovaries were found posterior to the uterus, and both formed cysts as large as a goose-egg and an orange respectively; the tubes

were both diseased. The appendages were closely adherent, and only freed with difficulty. It was found that the fibroid was not suppurating, but that one of the ovarian cysts was. The puncture-needle in one or more of the treatments had entered this cyst, which was almost directly in the median line, and was the "fluctuating nodule" which was detected at the first examination. The external sinus opened into this cyst, and when the tumor was removed it left the open mouth of the sinus behind, at the same time deluging the whole pelvis with the dark, virulent cyst contents. A clean removal of the uterus and both appendages was secured; the pelvis was flushed out most carefully and thoroughly, and a drainage-tube was placed at the opening of the sinus track. In spite of all precautions, the whole pelvis suppurated, and the woman died of septicæmia on the sixth day.

Certain it is that neither of these deaths ought to weigh against the operation of hysterectomy in cases where the conditions are fairly favorable. If cases are ever to be considered last-resort ones, these come in that class, and had I been operating for statistics rather than for the good of the women, nothing would have induced me to touch either of them.

As I have said, twelve cases recovered, and went home well women. With one or two exceptions, they were all complicated cases—short, thick pedicles, or pedicles which had to be manufactured; diseased tubes and ovaries; adhesions. One case had a nodule as large as the fist protruding into the vagina from the cervix. This mass had been sloughing for weeks, and the woman was deeply septic. The operation, which was performed at the Gynecean Hospital, was done in two stages. With knife and scissors the sloughing tumor was removed from the vagina. The instruments were quickly changed, and a supra-vaginal amputation finished the operation. So septic was the woman, that when the stitches were removed on the eighth day the whole line of the incision gave way and the intestines protruded in a mass. They remained out for about two hours before I could be found to replace them. Fortunately, my assistant, Dr. A. C. Wood, reached the hospital earlier than myself, went immediately to work, and was just replacing the protruding mass as I walked into the operating-room. In spite of this accident she made a good recovery, and is to-day well and at her usual occupation. Two of the twelve patients who recovered from the operation are dead. The other ten, as far as I know, are alive and in better health than they have been for years. The two deaths were due, in one case, to a subsequent operation for an ovarian cyst; in the other, presumably to heart disease. About six weeks or two months after her return home, while in apparent perfect health, she was suddenly seized with syncope, and was dead within half an hour.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 9th, 1891.

Dr. De Forrest Willard read a paper on Fractures and Injuries of the Spine in the Cervical Region, etc. (See p. 49.)

Dr. J. W. Baldy read a paper on Supra-Vaginal Hysterectomy. (See p. 53.)

DISCUSSION.

Dr. G. Betton Massey:—Dr. Baldy is to be commended for going into the subsequent history of his cases—a thing that is not often done. I must, however, take issue with him in regard to the case which I referred to him. I feel perfectly confident that in each puncture the needle went into solid tissue, and not into a cyst. The position of the nodule was that of a retroflexed uterus, a mass clearly presenting in the posterior vaginal vault. Another reason against the view of Dr. Baldy is that at no time was there any reaction from the puncture. An abscess formed, opening on the inner side of the thigh, but I certainly saw no septic condition. The temperature was not above 99.5°, and my idea of sepsis is connected with a higher temperature than that. This was her condition up to the time of operation, and in fact the woman felt so well that I had great difficulty in prevailing on her to have the operation performed. I think that, possibly, if the operation had been limited to a vaginal procedure, with the object of evacuating the pus, the result might have been different.

I think that Dr. Baldy should also have mentioned that three years ago, when the woman came under his observation, she was exceedingly tender on both sides in the re-

gion of these diseased appendages. This makes me think that the diseased appendages had been present for a long time, acting as a hindrance to the electrical work. After this condition was revealed by section the better plan would have been to remove the appendages and allow the healthy fibroid to remain.

I also want to take exception to the suggestion that the results of electricity are simply coincidences. Coincidences are very fortunate adjuvants in most of our work, but they are a mighty poor thing to depend upon. I do not think that the electrical workers throughout the world who have treated these tumors, could have gotten their results simply through coincidences.

It might also be said that the result obtained in a case which I saw yesterday was a coincidence. This was a dispensary patient that had been treated by abdominal electro-puncture as well as by vaginal electro-puncture and intra-uterine applications. Up to the time of the use of abdominal puncture, in which three needles were simultaneously employed, the progress was slow. She was quite lame from pressure on the crural nerve, and possibly from diseased appendages. In this case operation was recently urged by Dr. Baldy. As the result of these punctures, and the use of a current of 100 to 200 milliampéres, she is now so comfortable that she has not time to come to the dispensary for further treatment, the tumor being very materially reduced in size. After being an object of charity for years, she is now earning a living at general housework within a half square of this hall.

Dr. Charles P. Noble:—My own experience with abdominal hysterectomy has not been very large, for the reason that most of the fibroids that I have seen have not especially troubled their possessors. The majority required only medical treatment. Probably not more than ten per cent. were especially troublesome, and many of the women did not know that they had any tumor. On the other hand, as we all know, fibroids can give rise to dangerous symptoms either from hæmorrhage or pressure.

In my work I have taken a view opposite to that of Dr. Baldy, particularly when the fibroid is from medium to small. If the symptoms demanded operation, I have felt that I was doing the patient the best service by removing the appendages and not disturbing the tumor. None of these cases have died, and the results have been all that could be desired. An objection to hysterectomy by the extra-peritoneal method is, that a weak spot is left in the abdominal wall which is liable to become the seat of hernia. This is one reason why I prefer removal of the appendages where it can be done. Where the appendages are diseased, particularly if pus is present and discharged into the pelvic cavity, this would influence me to remove the fibroid, particularly if it just about filled the pelvis. If this were not done, I should anticipate death from sepsis. It is practically impossible to wash out the pelvis if the tumor about fills it, and with the tumor present it is impossible to secure drainage.

I quite agree with those who urge early operations when the tumors are giving rise to trouble. I have witnessed some fifteen hysterectomies, although I have done but two myself. All of these cases have recovered. Where the operation is not complicated by adhesions, and where the patient is not broken down, I quite agree that the risk of the operation should not be greater than that of ovariotomy.

Dr. B. F. Baer:—I congratulate Dr. Baldy upon his success, and I believe that in the main I agree with him as to his advice in regard to operation. Where the appendages can be thoroughly removed, and the tumor is small, I should prefer to remove them, but in some cases they are so spread out that thorough removal is not possible. In such cases I prefer hysterectomy. The result in early hysterectomy is very good, almost as good as in ovariotomy, and I have become an advocate of early hysterectomy in the cases requiring operation. In my experience, fibroid tumors, as a rule, do give rise to trouble. The fact that the patient submits to an examination, and will submit to treatment by electricity, by puncture, and other methods of treatment more or less painful, and even to hysterectomy, shows that the disease does give rise to trouble. I cannot understand why it is that men of large experience say that fibroids are not attended with symptoms. It is seldom that fibroids actually kill, but often the patient would prefer death to a continuance of the suffering. When, therefore, the tumor is giving rise to symptoms, and is of such a nature that its removal is not very dangerous to life, and the appendages are readily *entirely* removable, I prefer hysterectomy.

Dr. Baldy did not discuss methods, and therefore I shall not take up that subject, except to say that I believe the pedicle should be treated intra-peritoneally whenever practicable—*i. e.*, when it is small. This certainly simplifies the operation, renders the after-treatment easier, and makes the

condition of the patient after recovery more satisfactory. The patient recovers as well, if not better, when the pedicle is dropped. In the case that died at the Polyclinic Hospital, I have thought the result might have been different had the pedicle been dropped. My impression is that the woman died of tympanites more than anything else, and, as is well known, the extra-peritoneal method of treating the pedicle is very apt to be followed by tympanites and obstruction of the bowel from traction on the rectum.

In regard to Dr. Massey's case, I can scarcely agree that the appendages could have been removed and the uterus left. One of the tubes was quite diseased and spread over the tumor. If any operation was indicated hysterectomy was the one, and the only portion of the technique that I would dissent from is the manner in which the pedicle was treated.

Dr. Baldy:—In regard to the treatment of the pedicle I shall only say that I prefer to treat it outside, and my experience has been such that I shall always employ the extra-peritoneal method. The advantages, both theoretical and practical, are in favor of this plan.

In regard to Dr. Massey's case, I can only theorize as to the point of the puncture. I think myself that the majority of the punctures extend into the fibroid, but I know that some of them had been into the cyst, thus infecting it. The cyst was densely adherent at the point of puncture. I do not think that a fibroid will always show where a puncture has been made.

I have not seen much tympanitis after hysterectomy. Those cases that get well do not have distention. Where there is septic peritonitis there is always obstruction. In both of the fatal cases that I have reported there was well-marked septic peritonitis. Neither can I agree in regard to the liability to hernia after this operation. I have seen only one hernia after hysterectomy, and that occurred at the seat of the drainage-tube an inch above the pedicle. Although I see many cases after abdominal section coming back complaining, I have not seen one case of hysterectomy with post-operative trouble.

Many operators prefer oöphrectomy, and always do it when it can be done. I prefer hysterectomy, and give it the preference. In some cases you cannot remove the ovaries, and in others you may not be able to find the ovaries. In the case of exploratory operation reported, I found one tube which was distended with a bloody fluid, but I could not find the corresponding ovary or the ovary and tube of the opposite side.

Sometimes fibroids do not give rise to symptoms. One case operated on had very few symptoms. The girl had been told that she had a tumor, and came determined to have an operation, feeling that she would die if the tumor were not removed. The tumor was large. There was little hæmorrhage or pain, but there was one point which would in the opinion of many justify operation, and that was that the patient was only twenty-five years of age and the tumor was growing rapidly. The vast majority of fibroids I have seen have been advised to have nothing done. In future, with my present experience, I would consider such advice, in many of these cases, as unjustifiable.

Selected Formulæ.

SORE MOUTHS OF NURSING WOMEN.

℞
Listerine.....f℥ ij.
Glycerini.....f℥ ij.
Aquæ menth. pip.....f℥ ij.
M. Sig. Use a mouth wash two or three times a day.

—*Weekly Med. Rev.*

A LOTION FOR THE ALOPECIA FOLLOWING ACUTE DISEASES.

The following formula is given (*L'Union Medicale*) as a preventive of the alopecia which is observed during convalescence from grave acute diseases:

℞
Alcohol, 80 per cent.....℥ 2½.
Camphorated alcohol.....℥ 1¼.
Rum.....℥ 1¼.
Tinct. of cantharides.....℥ 1¼.
Glycerin.....℥ 1¼.
Essence of sandalwood, wintergreen and roses of each.....gtt. v.
Muriate of pilocarpine.....gr. vijss.

If the hair becomes dry, inunctions of oil of sweet almonds or castor oil may be made from time to time.—*Univ. Med. Mag.*

HEADACHE.

In many cases rebellious to all other medication, Pescarolo has obtained good results with the following mixture:

℞
Antipyrin.....grammes iv.
Phenacetin..... " ij.
Antifebrin.....gramme j.

He supposes that the favorable action is due to a new body which is formed in the mixture.—*Nouveaux Rémedes*, June 8, 1891.

COMPOUND WINE OF CREASOTE.

Dr. Fraenkel (*Il Raccoglitore Medico*, No. 14, 1891) gives the following to tuberculous

patients whose temperature is not high and in whose sputa the bacilli are not numerous:

℞ Creasote..... ..grammes xv.
Tinct. gentian..... " xxx.
Alcohol..... " cclv.
M. Two or three tablespoonfuls a day.

TREATMENT OF SWEATING HANDS.

The *Journal de Medecine* gives the following:

℞ Tinct. of belladonna.....ʒ j.
Cologne water.....ʒ j.
M. Add a little glycerin at the moment of using, and with the mixture rub the hands strongly. The hands should first be washed in soft water and thoroughly dried.

TREATMENT OF SYPHILIS DURING PREGNANCY.

E. Besnier recommends the following course of treatment:

1. Tonic medication. Good food, syrup of the iodide of iron, preparations of quinine.

2. Specific medication. Give every day one pill, as follows:

℞ Hydrargyri bichloridi.....gramme 0.010.
Extracti opii..... " 0.005.
Extracti gentianæ..... " 0.005.
Glycerinæ.....q. s. ut ft. massa. M.
Sig. For one pill.

3. At the same time prescribe iodide of potassium is doses of 0.50 to 1.0 gramme (7½ to 15 grains).

This treatment in continued throughout pregnancy, and the increase in the weight of the patient will testify to its efficiency.—*Revue Médico-Chirurgicale des Maladies des Femmes*, July 25, 1891.

FOR BLENORRHAGIA.

In the treatment of this disease, P. Thiery, (*Anal. de Malades Genito-urinaires*) recommends during the first period, abortive injections of nitrate of silver, and during the second period injections of iodoformated oil, frequent bathing, alkaline drinks, good diet, etc. After urination the following formula should be employed for injections:

℞ Iodoform, finely powdered.....grammes x.
Oil sweet almonds or glycerin. " lx.
A disinfectant substance, such as eucalyptus, vanilline, etc.q. s.
M. Sig. A syringeful of 10 c.c. is to be injected, and the injection kept in for 10 minutes.

—*La Médecine Moderne*, November 19, 1891.

ANTIPRURITICS IN URTICARIA.

Quinquad (*Deutsche Medicinische Wochenschrift*, 1891; No. 32).

Lotion.

℞ Boric acid.....grammes xxx.
Chloral hydrate..... " v.
Distilled water..... " clxxx.
For external use.

Dusting-powder.

℞ Salicylic acid.....grammes v.
Zinc oxide..... " xv.
Powdered starch..... " xxx.
For external use.

At the same time, alkalis are administered *internally*, and if these fail to produce an effect, sodium arseniate.

VARICOSE ULCERS.

Dr. J. Braun (*Lo Sperimentale*, No. 14, 1891) speaks highly of the following salve:

℞ Zinc. oxyd.....ʒ iv.
Lanolin.....ʒ iv.
Ung. emmolient.....ʒ jss.
M. f. ung. Apply locally on a piece of cloth a layer of the thickness of a knife-blade and over this a bandage.

Keep the patient abed until the ulcer has healed. If the ulcer has an unhealthy appearance the dressing should be removed three to four times daily.

The unguentum emmoliens of the Austrian Pharmacopœia is composed of white wax, 10 grammes; spermaceti, 20 grammes; oil of sweet almonds, 80 grammes; rose water, 20 grammes.

TREATMENT OF HYPERIDROSIS.

In the *Revue Général de Clinique et de Thérapeutique*, the following prescription for sweating of the hands and feet is given. The application is to be made night and morning. The part is first washed with hot water and immediately afterward the following ointment is applied:

℞ Ichthyol.....ʒ j.
Vaselin.....ʒ jss.

ANTISEPTIC ADHESIVE OINTMENT.

The following is an antiseptic adhesive ointment used at the hospital St. André:

℞ Zinci oxidi.....gr. ivss.
Zinci chloridi.....gr. xxijss.
Gelatinæ.....ʒ v.
Aquæ.....ʒ vijss.

This dressing protects the surface of wounds and dispenses with the use of bandages after operations. It is especially of service for the dressing of wounds on the face.—*Gaz. Hebdomadaire des Sciences Médicales*, August 16, 1891.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

Prof. M. V. Soubbatine (*Il Raccoglitore*, No. 12, 1891) employs the following in epidemic cerebro-spinal meningitis:

℞ Sodol. pur.....grammes 3.
Acetanilid..... " 1.80.
Sufficient for twelve pills. Three or four during twenty-four hours.

Soubbatine cured one severe case and Kratow saw rapid recovery follow in two cases after the use of these pills.

LEADING ARTICLE.

PEROXIDE OF HYDROGEN IN THE TREATMENT OF DIPHTHERIA.

The success which followed the use of peroxide of hydrogen as a solvent and antiseptic in the treatment of ulcers and suppurating cavities soon suggested its employment in diphtheria. When we reflect that this substance was discovered in 1818 and that it has many times been advocated by experienced observers, it seems strange that its value was not earlier appreciated. During the past five years, however, it has taken a prominent place among antiseptic and germicidal remedies, and from the present expression of medical opinion it is certain that its usefulness will be greatly extended.

The evident advantage of peroxide of hydrogen over all other substances having the power of destroying disease-germs is its almost entire harmlessness and the readiness with which it can be employed in the various cavities of the body, as well as externally. Its efficacy being due to the potency of the nascent oxygen liberated when it is brought in contact with organic matter, it more thoroughly and safely reaches the substances we wish to destroy than any other agent of its class.

While there are some expressions of doubt of the ability of this substance as a germicide, there is, on the other hand, no question that it is in this respect one of the most powerful agents known to the bacteriologist. When it is remembered that the medicinal peroxide of hydrogen should be of fifteen volumes strength and that but few specimens in the market are of over five, it is not strange that the results obtained from its use have not been universally satisfactory. Surely no more can be expected of this substance if in too weak solution than of the now popular bichloride under the same circumstance. Regarding the proof of its germicidal power, we would refer to the experiments of Miguel who found, after a long series of carefully conducted observations

that only two other substances are more powerful germicides than this; the two being the biniodide of mercury and the same salt of silver. He thus accords to the peroxide of hydrogen greater germicidal strength than that possessed by bichloride of mercury. These researches have been repeatedly confirmed, and it has even been shown that it is positively destructive to spores, the most difficult of organic matter to destroy. Gifford found that a contact of forty-five seconds was sufficient to kill adult anthrax spores.

In the local treatment of diphtheria we have three primary indications: First, to disinfect the discharges and thus prevent the absorption of septic substances; second, to destroy the disease-germs; third, to remove the false membrane. From the present state of our knowledge concerning the properties of peroxide of hydrogen, it seems that in it we possess a substance which largely, if not entirely, fulfils these indications. Moreover, when we add that it is harmless when taken internally, easily applicable to all varieties of the disease and to all ages of the patients, certainly no local application of which we are aware so fully meets our wants.

The literature of the subject offers much valuable information respecting its utility in this grave affection. For instance, Dr. Bleyer says: "While the membrane is thin and friable, the action of this agent is thorough, quick and effective; the deposit melts down before the contact of it like sugar in water, to be reproduced in a short time and again removed until the diseased tissue beneath can be plainly seen free from this characteristic covering." Such illustrations might abundantly be given.

What is the best method of applying this substance? The answer to this question will be modified by many circumstances, such as the age and tractability of the patient, the location of the membranous deposit, etc. If the case is an adult or a child who will co-operate with the physician, the peroxide is best applied directly to the parts by a cotton wad or brush, which is far more effectual than the spray or gargling, since it mechanically removes the outer and most toxic portions of the membrane and permits of immediate penetration of the peroxide to the deeper layers or even to the mucous membrane. Such applications should be followed by similar ones of the bichloride of mercury. In case of nasal complication, it must be applied by means of insufflation or injection to the affected parts. Atomizers can now be had specially constructed to project the spray to the posterior nares, and by the same means, or by a syringe, or eye dropper the peroxide can be applied through the anterior nares. In cases of children where the resistance to the use of the probang is so violent as to render the method inadmissable or undesirable, the pharynx, as well as the nasal chambers, may be flushed by means of a common syringe, a current being projected through each nostril. Should the nose become stopped up it must be cleared by a pledget of cotton on a suitable instrument before the injection is attempted. Where the applications can be made by this method through the mouth, the current should be directed to the back of the tongue, to the larynx and to the posterior nares. Such injections are followed immediately by the formation of a frothy discharge which arises from the evolution of nascent oxygen by contact of the peroxide with the septic organic substances. In fact, the amount of the froth is a fair index of the amount of mucous membrane involved, and the disappearance or increase of the false membrane is at once indicated in the quantity of this discharge.

The evidence available certainly indicates that hydrogen peroxide will be found to be the most valuable of all substances in our armamentarium for the local treatment of diphtheria, but it is of pre-eminent importance that only absolutely reliable preparations should be used, which should be fresh, free from an excess of acid and of full fifteen volumes strength. It seems almost needless to say that the preparation should be kept in a cool place and that it rapidly deteriorates with age, and when exposed to the atmosphere.

CORRESPONDENCE.

PHYSICIAN AND APOTHECARY—DR. WM. BULLEYN.

TO THE EDITOR OF THE MEDICAL AND SURGICAL REPORTER:—Dr. G. Granville Faught in your issue of November 14th brings under the notice of your readers the name of Dr. Wm. Bulleyn, whose works—"The Government of Health," 1559, 800; "A Regimen Against the Pleurisy," 1562, 800; Bulleyn's Bulwark of "Defense Against all Sickness, Soreness and Wounds, that dooe Daily Assault Mankinde," 1562, 800; "A Dialogue Both Pleasant and Pietifull, wherein is a Goodlie Regimen, Against the Feuer Pestilence," 1564, 800—prove him to have been far in advance of his contemporaries.

He was born in the early part of the reign of King Henry the VIII, and was educated at Cambridge. Afterwards he went on a tour through Germany and Scotland where he pursued his favorite study, botany.

In the year 1888 the Early English Text Society published a re-print of "A Dialogue Against the Feuer Pestilence," from the edition of 1578 collated with the earlier editions of 1564 and 1575, under the editorship of Dr. Mark W. Bullen and A. H. Bullen. The work is valuable as containing the narrative of "*Mendasc*," the original of Swift's "*Splendide Mendasc*," who describes a "fletyng Island swymming about the sea, by what means I knowe not, whether occasioned by corke, wooll, &c.; it would by the winde, shifte from place to place. Sume said it was a shred of the bankes of Paradise."

From a medical point of view the dialogues between the sick merchant, "*Antonius*" and the physician Maister "*Tocrub*," and the apothecary "*Crispine*" and "*Tocrub*," are interesting.

Physician and apothecary on their way to the patient are thus described by a citizen: "Thether euen within this twoo howers I did see Maister Tocrub solmonely ridyng upon his mule, with a side goune, a greate chaine of gold about his necke, his apothicarie *Crispine*, a neighboure's childe borne hereby in Barbarie, and his little lackey, a proper young applesquire called *Pandarus*, whiche carrieth the keye of his chamber with hym. These are all gone in at the gates to that noble Italian."

The physician directs the attendants to "Drawe the fountaines, open the luket of the windowe, set sallowes about the bed besprinkled with vinegar and rose water. Take off that hot mantle; let his head and shoulders be bolstered up."

"*Antonius.* To what persones I praie you, doeth the pestilence come." "*Medicus.* Moste chiefly to theim under the place infected, then to sluttishe, beastly people, that keepe their houses and lodyngs uncleane, their meate, drinke, and clothyng moste noysome, their laboure and traudile immoderate; or to theim which lacke provident wisdome to presente the same by good diete, ayre, medicine, &c." * * * * When there doth come a "sodaine alteration or change in the qualitie of water, * * * * * * or when strong windes doe carrie pestilent fume or vapours from stinkyng places to the cleane partes, as bodies dead of the plaugare unburned. * * * * * This is a dispersed pestilence by the inspiration of the ayre."

I am Sir, Yours Truly,
GEORGE A. FOY, F. R. C. S. I.

PROMISCUOUS SPAYING OF WOMEN.

EDITOR OF THE MEDICAL AND SURGICAL REPORTER:—In the issue of the REPORTER for December 12th, 1891, Dr. Noble criticises my article on the removal of the ovaries of women. If the Doctor had read the article a little more carefully, he might have observed that I referred to "a certain class of ambitious young surgeons, each striving to count the greatest number of abdominal sections." This, it is needless to say, does not include "the worthy successors and followers of McDowell, Atlee, Sims, Wells, Keith, etc."

My object in bringing the subject to the attention of the profession, was not to make baseless charges against respectable gynæcologists, as my critic would have it, but to prevent, if possible, women from being unnecessarily mutilated by would-be operators. The fashionable gynæcologist would no doubt use more elegant terms than unsexed or spaying for castration of the female, but to the general profession these terms seem to be well understood and wonderfully expressive. Only a few days ago, a woman, the mother of four children, applied to me to have the ovaries removed, that she might have no more children. I tried to dissuade her from her purpose, but she seemed determined to accomplish her object, and informed me that she knew of several women who had gone through the operation, and that she expected she would have no diffi-

culty as she was prepared to pay liberally for it.

This, you will observe, is another side of the same subject, and shows conclusively, at least to me, that there are certain parties who follow the profession of "The promiscuous spaying of women."

Very respectfully, yours,

WM. C. TODD.

BOOK REVIEWS.

THE SUPREME PASSIONS OF MAN. By PAUL PAQUIN, Late Professor of Comparative Medicine, and Director of the Bacteriological Laboratory, Missouri State University; Member of the American Public Health Association; the American Medical Association; Editor "Bacteriological World," Etc., Etc. Published by The Little Blue Book Company, Battle Creek, Mich., 1891.

This little book is one of a series of publications, by the Little Blue Book Company, which is intended to instruct the masses regarding various scientific subjects, and these subjects are presented in plain and simple language entirely suitable to the class of readers for whom the series is intended. The present volume is a freely expressed talk upon science, religion, morality and medicine, especially as they have to do with the *supreme passions* of the race. The author found it necessary, in accord with his views of the existing moral state of society, to reveal to the public eye the most common of social vices, and to his credit we will say that in general this has been done with considerable tact and delicacy of expression. The intent of the author is to prove that the passions of man are directly due to pathological nutrition, the results of wrong methods of living, eating and drinking, and that religion alone is powerless to cope with these passions. He shows how science and religion together could make the world a better place to live in, and demonstrates logically how food is the primary cause of racial characteristics, and of the development of the unnatural passions. A chapter is devoted to his theory of the causation of alcoholism, morphism, nicotism, etc., and is well worth the reading. While we cannot agree with some of the views expressed, the book as a whole contains many plain truths, and is a strong argument for better and more careful methods of living. It may be possible that it will do good to a certain class of intelligent readers, but it is certainly not a book to be carelessly read and condemned because it speaks plainly and truthfully of frightfully common human vices, and for the same reason it is possible for such knowledge to do some harm to pure, innocent minds. It is certainly one of the most vexing questions of to-day to decide just how the public generally should be made acquainted with such scientific truths as are treated of by the author of this book. We would heartily recommend its perusal to the profession as a popularly arranged contribution to sociological literature; and some parts of it will be found interesting because of ingenious theories respecting the growth of the passions. It is one of the books which are the outcome of the life-work of the author, and one may read in every page the effects of the writer's work in bacteriology and microscopic anatomy, just as the author of "Natural Law in the Spiritual World" combined in his book the results of his theological and scientific occupations.

A TEXT-BOOK OF PHYSIOLOGY. By M. FOSTER, M. D., LL. D., F. R. S., Professor of Physiology in the University of Cambridge, England. Fourth American from the fifth English edition, thoroughly revised. Philadelphia: Lea Brothers & Co. Octavo 1072 pages, 282 engravings. Cloth, $4.50; Leather, $5.50.

The appearance of another edition of Foster's Physiology again reminds us of the continued popularity of this most excellent work. There can be no doubt that this text-book not only continues to lead all others in the English language, but that this last edition is superior to its predecessors. It is evident that the author has devoted a considerable amount of time and labor in its preparation; nearly every page bearing evidences of careful revision. Although the work of the American Editor in former editions has been by the author largely adopted in a modified form in this revision, much was still left for the former to render the work fully adapted to the wants of our American students, so that the American edition will undoubtedly continue to supply the market on this side of the Atlantic. The work has been published in the characteristic creditable style of the Lea's, and owing to its enormous sale, is offered at an extremely low price.

PHOTOGRAPHS OF THE BACILLUS LA GRIPPE were presented to the Association Francaise pour l'Avancement des Sciences by M. Teissier, of Lyons, and mentioned in *Le Progres Médical* of October 3d. This culture and inoculations with it are very peculiar and interesting. It produces all the various symptoms of la grippe and even pus.

PERISCOPE.

THERAPEUTICS.

THE TREATMENT OF HÆMOPTYSIS.

Professor H. Nothnagel, publishes in a Vienna medical journal an interesting paper on the treatment of hæmoptysis. The first thing, he says, is absolute rest. If the loss of blood is at all serious, the patient must not utter a sound; if it is necessary he should speak, he must only whisper, or better still, write down everything he wants to communicate. He must not be allowed to see visitors, and the sick-room must be kept at an even temperature. The patient must take nothing warm, nor anything likely to excite or irritate. The best food for the first two days is cold milk. Regular diet may then be resumed gradually, but all food which might increase the action of the heart must be avoided in future. Formerly an opinion prevailed that the patient should be allowed to cough, the retention of the blood being supposed to be hurtful, as it was believed that tuberculosis was a consequence of hæmoptysis, but this opinion is quite erroneous. On the contrary, one of the first indications is to suppress all inclination to cough as much as possible, for which purpose morphia is the best remedy. Should the hæmoptysis not cease, other remedies must be applied. The author first mentions those remedies which ought to be eschewed, and the use of which is occasionally a physiological error. The first to be banished is perchloride of iron, the action of which on the blood is to cause it to coagulate and to form a thrombus. In the form of inhalation it would be simply useless but for the great danger in allowing a patient suffering from hæmoptysis to draw a deeper breath than absolutely necessary for respiration. The liquor ferri, if administered internally, is, according to some, not absorbed at all, but, even if it be so, it would only tend to increase the hæmoptysis. The same may be said of tannic acid and of alum, which contract the blood-vessels only when diluted to $\frac{1}{6}$ per cent., and are consequently useless for hæmostatic purposes as well as for inhalation. The author dispenses altogether with inhalation in hæmoptysis. The only two hæmostatic remedies he recommends as useful are ergotine and acetate of lead; the first may be used internally and in hypodermic injections, the latter may be given in conjunction with opium. Another remedy which he mentions, but of which he has himself no experience, is hydrastis canadensis. A few years ago hypodermic injections of atropine were recommended, and Prof. Nothnagel has occasionally seen them effective. No objection can be raised to half a teaspoonful of common salt when no other remedy is at hand. Hæmorrhage from the lungs is certainly sometimes arrested by its use, but the author is not quite sure if the success is *post hoc or propter hoc.* Nor is he certain whether, as supposed by some, a reflex irritation of the pulmonary vessels takes place. This theory is certainly physiologically feasible, as recent experiments have shown that sensory excitement in some parts causes the blood-vessels in other parts to contract. An application of ice, for instance, to the abdomen causes anæmia of the mucous membrane of the larynx. A very common remedy is the application of cold; but the ice-bag is, according to the author, of very doubtful value, as it is impossible to assume that the cold acts directly on the bleeding surface, for we do not know to what depth it penetrates. If the cold does act hæmostatically, the effect must be due to irritation of the skin. Professor Nothnagel warns us, however, that in some people the application of cold to the thorax causes cough, which is far more dangerous than the doubtful contraction of the blood-vessels can be useful. An extreme and heroic remedy is venesection. It is a well-known fact that wounded soldiers faint from loss of blood, when the hæmorrhage immediately stops, and a similar observation has been made in metrorrhagia and hæmoptysis.—*Lancet.*

HYPODERMIC INJECTIONS OF CORROSIVE SUBLIMATE IN DIPHTHERIA AND SCARLATINA.

Dr. J. Jacontini (*Morgagni*, 1890) administered by injections 1 centigramme of corrosive sublimate in eight or nine days during an epidemic of scarlatina. The fever was reduced and at the same time the manifestations in the throat were modified. Encouraged by these results the author used this treatment in two cases of diphtheria with the satisfaction of obtaining a rapid attenuation of the morbid phenomena and followed by cure.

MOUTHWASH FOR CARIOUS TEETH.

A mouthwash said to prevent dental caries is as follows: tannin 5 grammes, tincture of iodine and tincture of myrrh, of each

2.5 gramme; potassium iodide, 1 gramme; rose water, 180 gramme. The mouth is rinsed every morning with one teaspoonful to a glass of warm water.—*Bull. de Therapeut.*, 1891, cxx, p. viii.

OSMIC ACID IN GOITRE.

Dr. S. Auerbach relates the case of a young woman of 25, suffering from goitre (the variety and dimensions not stated), in which he resorted to a "combined method" of treatment, including, *a*, a parenchymatous injection of a solution of osmic acid (1 grain to 2 drachms of distilled water), a syringeful once daily or every other day; *b*, local massage, for 15 minutes, once daily, and, *c*, the internal administration of iodide of potassium. By the end of three weeks all subjective symptoms disappeared, while the tumor was found to have greatly decreased in bulk (was half the size compared with the period before the treatment). Unfortunately, the woman was subsequently lost from sight.—*I etopis Khirurgitcheskaho Obshtchestva v Moskve*, No. 6, 1890, p. 505.

QUININE POISONING.

Dr. A. Erlenmeyer reports in the *Centralblatt für Nervenheilkunde* a case of poisoning with this drug which is of some interest. The author had previously observed abolition of the reflexes in several patients who were taking large doses of quinine, but in the case under consideration the symptoms were those of an intense reflex irritability. The patient, aged forty-two years, had taken at one dose a gramme of quinine (about fifteen grains), and on the following day two grammes in divided doses. Examination of the reflexes at this time, by tapping and the other tests, brought on general convulsions, with violent contractions of the arms and the whole body. Leaving off the medication for twenty-four hours would cause a disappearance of the nervous excitability.

TREATMENT OF PNEUMONIA IN DIABETICS.

Dr. Merklen (*Gazzetta degli Ospitali*, No. 56, 1891) regards pneumonia as one of the most dangerous complications of diabetes. It appears in diabetes without any initial chill, pains or dyspnœa; sometimes its presence is marked by intense dyspnœa, due to congestion, which may become so severe as to kill the patient in one to two days—the fulminant diabetic pneumonia of Bouchardat. It may terminate in pulmonary abscess or gangrene, yet all cases are by no means fatal. The writer narrates a case where the sugar disappeared from the urine at the beginning of the disease, to reappear during convalescence. The same was true of the polyuria, hence in such cases the reappearing of the polyuria and sugar in the urine are favorable signs. In his case there was no albuminuria. The writer prescribed caffein, 1 gramme (15 grains) a day hypodermatically, as a diuretic and heart tonic; two or three quarts of milk daily, and 1½ grammes (22 grains) of the sulphate of quinine, together with revulsion to the chest.

CURES FOR DRUNKENNESS.

There appears to be some excitement in Illinois at present over the gold cure for drunkenness. Chloride of gold is said to be the remedy, and the *Western Druggist* says there is little new about that, for a Dr. Gray, of La Porte, Indiana, practices the following method of cure regularly. When he receives a patient he sets in his room a bottle containing a pint of good whiskey, instructing the patient that he can take all he wishes. The doctor immediately commences and gives him four hypodermic injections each day, each containing one-tenth of a grain of the chloride of gold and sodium, and one-fortieth of a grain of nitrate of strychnine, and gives a mixture to be taken by the mouth containing the same with some atropine. The formula for the mixture is:

℞

Sodio-auric chloride	gr. xij.
Ammonium chloride	gr. vj.
Strychnine nitrate	gr. j.
Atropine	gr. ¼.
Fl. ext. cinchona compound	℥ iij.
Fl. ext. coca	℥ j.
Glycerin	℥ j.
Water	℥ j.

Mix, and take a teaspoonful every two hours when awake.

He sees the patients four times a day and rapidly increases the gold and strychnine until the symptoms show that they are getting all they will bear. The first day the patient drinks pretty heavily of the whisky in his room. The second day he begins to lose his desire for it. By the evening of the third day or the morning of the fourth he is totally sick of it, and will not take any more. The treatment is carried on from three to six weeks. It seems to be a great success. We are frequently asked what Haines' golden specific is. A formula for producing a powder said to resemble this preparation, was contributed to the *Druggists' Circular* some time ago, and is as follows:—

℞ Bark of bayberry root.....parts xvj.
Ginger ..... " viij.
Capsicum..... " j.
Reduce to a fine powder, and mix thoroughly.

—*Chem. and Drug.*

TREATMENT OF URÆMIA.

Prof. Tissier (*Gazzetta degli Ospipitali*, No. 25, 1891), recommends:

1. Lavage of the stomach.
2. Inhalations of oxygen.
3. When the vomiting threatens to interfere with the nourishment of the patient, one to two drops of tincture of iodine in a spoonful of water are indicated. Creasote and menthol have also been successfully used. Lecorche and Telamon have succeeded in arresting the incoercible vomiting by lactic acid:

℞ Acid lactic.....mxv--xxx.
Syrup menthæ pip.....fl℥ j.
Aquæ destillat.....fl℥ iij.

Bouchard advises rigid intestinal antisepsis.

4. For the treatment of the cerebral and nervous symptoms he advises:

For the eclampsia, chloroform by inhalation, chloral, the bromides—preferably the sodium bromide, bromide of potash being contra-indicated on account of the potash which it contains—paraldehyde, opium and its derivatives, administered with caution on account of the impermeability of the kidneys and their tendency to accumulate.

Rosenstein and Rossbach use the nitrate of sodium:

℞ Sodii nitrat.....gr. xxx.
Syrup cortic. aurantior.....fl℥ j.
Aquæ..... .....fl℥ iij.
Two to three teaspoonfuls daily.

Labaure, Lagrave and Huchard recommend amyl nitrate, which, however, is contra-indicated when there are vascular changes present.

5. In uræmic asthma tincture of guebracho or aspidospermine are to be recommended. Lecorche and Talamon regard venesection and morphine as the true remedies in this stage. Intra-venous injections of sodium salts are useful. If the heart be weak with dyspnœa, then use such heart tonics as caffeine, adonidine, digitalis and camphor.

THE TREATMENT OF SENILE GANGRENE.

In a recent issue of the *Deutsche Medicinische Wochenschrift*, Prof. Haidenhain presents his views on this subject, which are based on a careful study of twenty-five cases of senile gangrene of the lower extremity, the majority of which occurred in diabetics. It is a well-known fact that this form of gangrene is characterized by especial severity, so that the author's rules for treatment are worthy of careful consideration. He advises that as long as the gangrene is confined to one or two toes we should abstain from surgical intervention, and wait for a line of demarkation to form. Local antiseptic measures and elevation of the limb are all that is required, and we are especially warned against the detachment of the gangrenous portions with the scissors and forceps, which tends to increase the inflammation. If the gangrene spreads to the dorsum or sole of the foot, we should adopt Hutchinson's recommendation and amputate at the thigh, making as small skin flaps as possible. An extensive experience has shown that amputation below the knee in these cases is apt to be followed by gangrene of the flaps, which, if it does not lead to a fatal termination, renders a second operation necessary. If high amputation is deferred until the development of fever and suppuration the prognosis becomes the more unfavorable. While it is true that a successful result has sometimes been obtained by amputating below the knee, the weight of testimony is decidedly in favor of the high operation.

ANTIPYRIN IN THE TREATMENT OF CHOREA.

Leroux (*La Semaine Médicale*, August 12, 1891) obtained favorable results in forty-one of sixty cases of chorea treated with antipyrin. In the favorable cases, the disease terminated on an average at the end of forty-five days—the usual duration of chorea being sixty-six days. In nineteen cases, the results were not favorable, either because the disease proved refractory to antipyrine or was prolonged as post-choreic tic, or because the treatment was pursued irregularly, or was suspended on account of an intercurrent affection or of an intolerance of the remedy. Recurrences and relapses were, however, frequent, notwithstanding the continuance of the treatment. Forty-five grains (daily) constituted the minimum dose from which favorable results were obtained. In some instances, it was necessary to administer from sixty to seventy-five, and even ninety grains. The treatment was begun with from fifteen to thirty grains; for children of from eight to ten years, the dose was speedily increased to from sixty to seventy-five grains; for children of from ten to twelve, to from seventy-five to ninety grains. Some cases yielded at

once to doses of from forty-five to sixty grains; but if at the end of from eight to ten days there was no change, the dose was increased in accordance with the age of the child. If, finally, at the end of a month doses of from seventy-five to ninety grains brought about no notable amelioration, no more was hoped for from its administration. Notwithstanding the prolonged administration of large doses of antipyrin, not a single grave accident occurred.

TUBERCULIN IN LARYNGEAL PHTHISIS.

Dr. Struebing (*Deutsche Med. Wochen.*, October 8th, 1891) records the cure of a case of laryngeal tuberculosis brought about by tuberculin. There was in the case well-marked evidence of pulmonary phthisis, and the treatment is reported to have brought about an improvement in the condition of the lungs. On examination of the larynx the left vocal cord was seen to be occupied by an ulcer of considerable size, around which was much swelling and redness of the mucous membrane. The patient was extremely hoarse. After the first injection there was evidence of local reaction—swelling and injection of the laryngeal mucous membrane, and subjectively, increased hoarseness and pain in larynx, especially on swallowing, with slightly marked symptoms of stenosis. After the fourth injection no further reaction was observed. Rise of temperature was noted only after the first few injections, and then it was slight. When about nine had been given the ulcer appeared to have a cleaner look; later, improvement in this direction was undoubted; the edges, moreover, were much less prominent, and presently became obliterated, the floor of the ulcer passing insensibly into the healthy tissue around. It now became gradually smaller, and was no longer visible after the forty-third injection; this consisted of 0.1 g. tuberculin. The entire amount used up to the date of cure was 1,573 g.—*Brit. Med. Jour.*

LOCAL ANÆSTHESIA PRODUCED BY INJECTION OF WATER.

Dr. C. L. Schleich has made experiments of himself and his assistants, which demonstrate that the hypodermatic injection of simple sterilized water produces local anæsthesia of several minutes' duration. The anæsthetic area becomes the seat of a white œdema similar to that produced by the sting of a mosquito, the extent of which depends upon the quantity of water injected. The technique of the procedure differs in no respect from the hypodermatic injection or medicated solutions; the syringe and skin are disinfected. The pain produced is no greater than that resulting from the injection of cocaine, depending upon the sensitiveness of the part, and may be almost entirely prevented by spraying the parts with ether at the time of injection. The needle is inserted slowly and parallel with the cutaneous surface. The anæsthesia is so complete that incisions may be made into the skin without the slightest pain.—*Deut. Medizin-Zeitung*, No. 66, 1891.

YEAST IN ENTERIC FEVER.

M. de Bavay's paper read before the Melbourne and South Australian Branch on the action of yeast on the typhoid bacillus contains an account of experiments in the intestinal canal of the human subject, he believes that he has been able to obtain a set of conditions under which the development of the typhoid organism is materially interfered with, whilst such poison as it does secrete is so utilized by absorption from the alimentary canal as to confer an immunity against the action of the more virulent poison. It will be remembered that in 1887 Dr. J. B. Buist brought forward a method of yeast inoculation against the action of small-pox; but his experiments at the time were not convincing, and, though undoubtedly exceedingly interesting, they were not, we believe, attended with any practical result. We shall now await with interest medical reports on the results of M. de Bavay's treatment, as only actual confirmation of the theory here put forth can enable any definite opinion to be pronounced. Those who heard the paper read at the meeting of the Melbourne Branch were apparently considerably impressed with a sense of its importance, and certainly both the argument and the work seem to have carefully carried out.—*Brit. Med. Jour.*

MEDICINE.

SPONTANEOUS SHEDDING OF THE NAILS IN DIABETIC PATIENTS.

Prof. Auché *Rivista Clinica e Therapeutica*, No. 4, 1891) communicates the results of his studying the development of this phenomenon in diabetic patients. First a hæmorrhage takes place into the tissue beneath the nail which, according to its amount, detaches the nail more or less extensively from

its bed. If the hæmorrhage be but slight, there appears a small and reddish film; if more abundant, the nail is raised from its bed, remaining attached only at the extreme lateral borders, until a new nail forms when the old nail is cast off. The writer is inclined to regard the spontaneous hæmorrhage as due to lesions of the peripheral nerves. His conclusions are as follows:

1. Diabetes mellitus, like tabes dorsalis, hysteria and various other affections, may, and often does, cause spontaneous shedding of the nails of the hands and more frequently those of the feet.

2. Shedding may take place in two manners. In certain cases the hæmorrhage and detachment occur without any preceding symptoms or disorder, when the diagnosis between syphilis and locomotor ataxia would be without the aid of concomitant symptoms, extremely difficult. In other cases subungual hæmorrhage may precede detachment. In such cases, the mechanism is similar to that observed in certain tabic patients.

3. These hæmorrhages are not only due to changes in the vessel walls, but also, in some cases, to lesions of the nerves found in the fingers.

MENIERE'S VERTIGO AND THE SEMICIRCULAR CANALS.

The experiments of Flourens, which seemed to attribute to the semicircular canals the *role* of maintaining the equilibrium of the body, have been controverted by others to such an extent as to make it appear doubtful whether that part of the labyrinth is the seat of the lesion which determines the so-called vertigo of Ménière. The peculiar character of the vomiting, the fact that the latter symptom may occur suddenly without nausea, after irritation of the membrana tympani, the intimate connections between the pneumogastric and the auditory nerve at their origin, renders it more probable that the vertigo and cardiac symptoms are due to a reflex action in the pneumogastric dependent upon a lesion in some portion of the auditory nerve. The term Méniére's disease serves more frequently to mark ignorance of the lesion which occasions a series of symptoms often analogous but which are under the influence of very different causes. —Sir Wm. B. Dalby, *Brit. Med. Journal*, and *Annales des Maladies de l' Oreille*, etc., vol. xvii.

Koch is Still at Work on Tuberculin, and hopes to make it gradually less and less deadly.

EXAMINATION OF THE EYES OF THE INSANE.

M. Roget (of Lyons) states that there exists in the greater part of the general paralytic a characteristic rigidity of the pupil. Besides excavation of the papilla, quite frequent in the normal state, should be regarded as the rule in those hereditarily predisposed, and in the insane who exhibit evidences of suicide. Finally, idiots and imbeciles, in respect to visual function, may be classed in two categories: The hypermetropic idiots are those whose infirmity dates back to uterine life; on the contrary, emmetropic and myopic idiots have become demented since infancy.

ARTIFICIAL NEURASTHENIA.

Dr. Von Pelizarva (*Deutsche Med. Woch.*) describes a condition which he has observed to come on in a patient undergoing the water treatment at mineral springs and to which he has applied the name of artificial neurasthenia. This condition has frequently been described as bath or spring fever, but the author of the present article says that it is undoubtedly a form of nervous disturbance resulting from the indiscriminate use of the bath and drinking of the mineral waters.

It is well known that there is a great difference in individual ability to react from certain shocks. At one time reaction from a cold bath would be prompt, at another there will be distinct loss of control of the will, shrinking and so forth, followed by depression and weakness. When such results obtain and the baths are persisted in the process will undoubtedly cause lessening of the resisting power of the nervous system. When it is remembered how great is the number of people ordered to the baths by physicians and how many go on their own account and take a regular course of treatment, in spite of the discomfort it may cause, it is not to be wondered at that patients return with neurasthenia or an exhaustive neurosis. The condition is soon established and it is for this reason that the author urges upon medical advisers sending patients to the springs, and also upon the physicians attending there, greater care in the selection of cases destined to undergo regular treatment. Due to the lack of the necessary foresight in this regard, Carlsbad, and Kissengen are prominent sites for the promotion of this form of nervous artificial neurasthenia.

SYPHILITIC DISEASES OF THE SPINAL COLUMN.

Dr. Jasinski (*Archiv. für Derm. und Syphilis*, No. 3, 1891) maintains (1) that syphilis of the spinal column occurs under the forms of periostitis, ostitis gummosa, caries, exostosis, and necrosis; and (2) that it is a relatively very rare affection when diagnosis is established beyond a doubt.

A number of personal cases are reported, one of perispondylitis syphilitica; one of gummous inflammation of the periosteum and bodies of the cervical vertebræ, which was cured by immobilization, with a plaster-of-Paris dressing, and inunctions combined with large doses of iodide.

Several instances of spinal affection in children are given and the literature of the subject is reviewed at some length.

THE ORIGIN OF EFFUSIONS.

Dr. G. Pisenti (*Riforma Medica*, June 12th, 1891) describes an experiment which serves to explain several points as to the origin of effusions. The method is simple, and one which can be easily demonstrated in the course of a lecture on pathology. The only preparation necessary is the following: A rabbit or guinea-pig is fixed in the retention apparatus, anæsthesia being produced either by ether or chloroform. An incision is then made along the linea alba about 4 inches long, so as fully to expose the abdominal cavity. The intestines are then raised and turned over to the left, thus exposing the portal vein, into which a cannula is tied. This cannula is next placed in communication with a reservoir containing either pure defibrinated blood, a mixture of blood and saline solution, or simply saline solutions (0.75 per cent.) The liquor should be kept warm, and the pressure measured by means of a manometer. The costal arch is then raised so as to expose the upper surface of the liver, and the artificial circulation is commenced under a pressure of about 2 mm. of mercury. In a few moments pale areas appear on the surface of the liver, which continue to increase as long as the circulation is maintained. If pressure be then raised a curious phenomenon is observed: numerous small drops of liquid exude through Glisson's capsule, and after a time run together, so that the surface of the liver becomes bathed in liquid. The rapidity of the exudation depends upon the pressure at which the artificial circulation is maintained. (1) There has thus been produced a true œdema from stasis, for supplying more liquid than can be removed by the efferent vessels, all the effects of a block in the circulation are reproduced, this effect increasing with any increase in pressure. (2) The same method can be used to demonstrate the production of exudation due to hydræmic plethora; by introducing simple saline solution all the effects of a hypo-albuminous condition of the blood can be obtained. In this case the effect on a single organ, the liver, will be similar to that produced on the entire body by the intravenous injection of large quantities of saline solution. It serves well to explain the origin of the acites so often seen associated with a watery condition of the blood. (3) It is well known that some tissues are more prone to œdema than others, and this is also illustrated by the above experiment, for of all organs that might be used the liver is that in which the phenomena can be best seen. It would appear, then, that the walls of its vessels are less resistant than those of other organs to the passage of liquids. (4) Lastly, from the rapidity with which exudation commences, it may be concluded that this can happen without any alteration of the vessel walls themselves, and this in opposition to the view held by some that exudation cannot take place without initial vascular lesions. To summarize, this experiment of Dr. Pisenti demonstrates (*a*) that increase of intravascular pressure plays an active part in the production of exudations (exudation of stasis); (*b*) that exudation may arise from alteration in the consistence of the blood (exudation from hydræmia); (*c*) that the histological constitution of the vascular walls varies from tissue to tissue, and from organ to organ; (*d*) that exudation may take place independently of any alteration in the walls of the vessels.—*Brit. Med. Jour.*

GOITRE—ITS PATHOLOGY, DIAGNOSIS AND TREATMENT.

Berry (*British Medical Journal*, June 13, 20 and 27, 1891) has made an extremely clear and valuable contribution to the subject of goitre.

He makes five varieties: (1) parenchymatous, (2) cystic, (3) fibro-adenomatous, (4) malignant, and (5) exophthalmic. All these varieties, except the last, which stands alone, clinically and structurally, run very much into each other, so that mixed forms are common.

From an extensive study of the probable causes of goitre, Berry concludes that its co-

incidence with limestone and calcareous sandstone districts everywhere in England is so marked that its appearance as an endemic disease in non-calcareous regions is doubtful. All attempts to produce goitre artificially have failed, from the experiments of St. Lager to those of the present day. Animals drinking solutions of the different forms of salts found in water from these regions, have never shown any sign of goitre, although goitre is common in lower animals in goitrous districts.

Yet the fact that goitre can be produced by water has been proved accidentally from human experimentation. For example, in a regiment of young soldiers, quartered in a goitrous village, there developed, in a large proportion of the men, goitres in a few months or even weeks. Again, a town has has received a new water supply, and shortly afterward goitre has broken out in a large number of the inhabitants. Conversely, a village afflicted with goitre has been relieved of that disease by changing its water supply.

There are "goitre-wells" on the continent, to which young men, who wish to be exempt from military service, resort; after drinking this water for a few weeks, they obtain goitres sufficiently large for them to obtain their wish.

Mere hardness in the water does not cause goitre. Berry believes that there is a definite relation between goitre and some poison in the soil, which is carried by drinking water. This may be some mineral ingredient, possibly a salt of some alkali or alkaline earth. From personal experiment he believes that it is not a salt of lime, magnesia or iron. Want of air and sunshine, climatic and atmospheric conditions, heredity, habits and intermarriage, have apparently no share in the causation of goitre.

The effect of goitre on the duration of life is small. In some cases pressure on the trachea causes death. Again, if bronchitis or some similar disease intervenes, the patient has a much smaller chance of recovery.

In regard to the treatment of goitre, the author believes that injections of various substances to excite sufficient inflammation to obliterate the vesicles of the gland, or to have some solvent action on the colloid contents, is not devoid of danger. Iodine is far preferable to every other substance; yet its injection has been followed in a number of cases by death. Internal administration of remedies is briefly discussed and dismissed. The use of setons was wisely abandoned long ago.

A noteworthy series of cases has been reported by Rydygier, of Cracow, in which ligature of the superior and inferior thyroid arteries on both sides has been performed. In sixteen cases the results were excellent, although the operation is a difficult one, and the patients have not been watched for sufficient time. Cystic or fibro-adenomatous goitres are less likely to be benefited by such ligation. Division and resection of the thyroid isthmus have been less successful; the operations have been followed by death in some cases, or the dyspnœa, for relief of which the operation was done, was unimproved. Total extirpation of the gland is not recommended on account of its grave dangers. Partial extirpation has been done by Berry, frequently with good results. *Mukulicz's resection*, which consists in removing the chief part of a lateral lobe, avoiding the recurrent laryngeal nerve by leaving the portion of the gland adjacent intact, has the advantage that it leaves sufficient gland tissue to prevent cachexia strumipriva, avoids hæmorrhage and injury to the recurrent laryngeal nerve, and removes the capsule of functionally useless gland tissue. There has never been a return of the goitre in the portion of gland in twenty-three cases operated on according to Mukulicz's method, nor impairment of health, although one case died of recurrent hæmorrhage and one required a tracheotomy.

In 550 cases of partial thyroidectomy only six present symptoms of cachexia strumipriva; five of these recovered and one died. In cases of cachexia strumipriva, transplantation of thyroid tissue, as done by Kocher, Horsley and Fenwick, can be tried. Pilocarpin, jaborandi and nitro-glycerin should be of service. In malignant goitre no operation but tracheotomy is advisable. Kocher has reported the results of 250 consecutive operations on goitre, with a mortality, if malignant and exophthalmic goitrous disease be eliminated, of 0.8 per cent. Cachexia strumipriva is the most important remote effect of thyroidectomy; the existence of this remarkable affection, following the operation, was drawn to the attention of the profession in 1883; its recognition had a great effect in modifying views held in regard to thyroidectomy. Berry believes it can be avoided by performing partial thyroidectomy.—*Univ. Med. Mag.*

CLINICAL STUDY OF THE CONDITION OF THE HEART IN TYPHOID FEVER.

Dr. L. Galliard, (*Archives Générales de Médicine*) took careful notes of the anomalies in the condition of the heart during an epidemic of typhoid fever in Paris, in 1880, while he was interne under Professor Hayem in the Saint Antoine Hospital. He had delayed publishing the notes, as he had hoped to have made further investigations on the subject, but circumstances prevented him, he simply gives the clinical notes of the cases as they were taken at the time.

The first case was one of sudden death at the end of the first week of the disease. The patient was progressing favorably, the temperature 37.8° C. in the morning, and 40.2° C. in the evening, when he became delirious, and after a short time died. No cause could be found in the *post mortem* examination to account for the death.

The second case was one of collapse on the thirteenth day. There had been profuse diarrhœa, and the temperature from 39.5° C. on the eleventh day, gradually sank to 36.1° C. in the armpit, and 37.4° C. in the rectum on the thirteenth. He presented all the appearance of a cholera patient, with cold extremities, livid face, almost pulseless, and no heart sounds to be heard. Under stimulating treatment he gradually recovered.

The third and fourth were cases of non-rhythmical intermittence of the pulse, the third exhibiting the intermission only on the day of entry [the eighth of the disease]. There was a murmur [systolic?] at the apex and at the base of the heart. In the fourth case, the intermissions continued from the 8th to the 24th day. There was slight albuminuria.

The fifth was an anæmic girl, in whom rhythmical intermissions occurred after defervescence—from the 24th, and lasting three weeks. There was also systolic murmur at the apex and in the pulmonary area. In the sphygmographic tracings there occurred an occasional double pulsation. The patient had also a slight relapse.

The sixth case was at first simply asthenic, with feebleness of the apex beat, and of the heart sounds. There were intermissions on the 24th day when the fever was abating. Pneumonia ensued, and the patient died. There was myocarditis.

The seventh case had untractable diarrhœa. At the end of the third week there was feebleness of the heart and faint first sound. Later, at the apex, the first sound could scarcely be perceived while heard distinctly over the sternum. There was also inequality and irregularity in the pulse beat. The patient died suddenly about the end of the fourth week. Myocarditis and vitreous degeneration of the voluntary muscles were found.

In the eighth case there was systolic murmurs at the base and apex observed on the eighth day of the disease, disappearing on the tenth from enfeeblement, and the patient died on the twelfth. There was myocarditis.

The ninth case was somewhat similar to the eighth.

In the tenth there were anæmic murmurs that persisted after recovery and the author points out the necessity to distinguish anæmic murmurs from murmurs arising in cases of myocarditis.

The next three cases are examples of the true cardiac form of typhoid fever. There is a general resemblance in all these cases—intermissions of the heart's action coinciding with the murmurs, or following on the disappearance of the heart's sounds, and feebleness of the apex beats. Towards the end the heart's action becomes irregular, accompanied by tachycardia, and is premonitory of a fatal termination, and finally syncope, preceding death. There were also complications in the lungs, kidneys, nervous system, etc. In the three cases given myocarditis was demonstrated in each one.

The last two cases of endocarditis, the murmurs appearing in the one case on the eighth day, and persisting after recovery, and in the other case acute endocarditis was diagnosed before the symptoms of typhoid fever developed, the murmurs persisting here also after recovery.

The author concludes with a few remarks on the causes of the cardiac phenomena, pointing out that, in addition to the local mischief, affections of various nerve centres would account for some symptoms. In treatment, he strongly recommends the judicious and bold use of digitalis.

SURGERY.

ARTHROTOMY IN OLD LUXATIONS.

V. Vaurossy (*Wien. klin. Woch.*, 1890, No. 50). V. reports from the Innsbruck clinic nine cases of old elbow luxations, and one each of shoulder and metacarpo-phalangeal of the thumb. The elbow luxations consisted of backward dislocation of both of the forearms. Either the external or internal epicondyle, or both, as in one case,

served as barriers to reduction by being forced into the joint. The longest duration of the luxation was twenty-four months. The younger the individual and the luxation, the more favorable the prognosis. The cartilaginous covering of the articular extremities of the bones suffers less in young individuals, in case of luxations of long standing, than in olders ones.

In performing arthrotomy in these cases, the joint was opened from both sides. The author, as a result of his experience, declares that by means of arthrotomy a much better result is reached than by a most economically planned resection. Subcutaneous separation of the intra-articular bands which form in these cases the author declares to be entirely insufficient.

MODERN RENAL SURGERY.

Dr. A. Obalinski sums up his views regarding the treatment of severe inflammatory affections of the kidneys and their sequelæ in the following way: 1. Suppurative inflammation of the kidney and surrounding structures indicates the operation of nephrectomy in order that free exit may be given to the purulent and other inflammatory excretions, and that the focus of the diseased may be thoroughly cleansed, and further extension of the suppuration to important parts, as, for example, the thoracic and abdominal cavities and the hipjoint, be thus prevented. In most cases the single lumbar incision, as was performed by Simon, will suffice, but when there has been extensive undermining of the peritoneum the formation of a large flap, as practiced by Bardenheur, is to be preferred, as such operation permits of ready access to all extensions of the main pus-containing cavity. 2. Urethral fistulæ should always be treated by removal of the corresponding kidney, provided the surgeon can assure himself of the existence of a sound renal organ on the other side. Nephrectomy in such cases is indicated, not only on subjective grounds and when, for instance, the external flow of urine cannot be restrained by any apparatus and the patient is thus prevented from following his occupation and from enjoying a comfortable existence, but also on objective grounds, since, notwithstanding the utmost precautions, an old ureteral fistula may result in suppurative inflammation of the corresponding kidney and of the adjacent soft parts. 3. Nephrectomy performed under these last mentioned conditions offers much less favorable prospects than in cases in which there is an absence of suppuration or of cicatricial adhesions. 4. There can be no doubt that, under equally favorable conditions, the transperitoneal method can be performed more rapidly and with greater ease than the extraperitoneal method of nephrectomy, and that the progress toward recovery is more speedy after the former operation. The transperitoneal method, however, is not applicable to every case, and should be reserved for those instances in which the mischief is confined within the capsule of the kidney, the extraperitoneal method being indicated when the suppurative process has involved the perirenal structures.— *Volkmann's Sammlung Klinische Vorträge.*

RESECTION OF THE SKULL IN TRAUMATIC EPILEPSY.

Dr. A. Garibaldi (*Gazz. degli Ospitali,* October 4th, 1891) reports the case of a man, aged 23, who, ten years previously, had fallen from a considerable height on his head, sustaining a compound comminuted fracture of the skull in the right frontoparietal region. After this accident he became subject to epileptic attacks; these were at first partial, starting from the left leg, particularly the flexor muscles; during them the man was dazed, but did not lose consciousness. The attacks gradually became more frequent, until they occurred two or three times a week. On examination an irregular cicatrix was found on the right side of the skull directed obliquely from without inwards, from below upwards, and from behind forwards. The scar was about 8 centimetres in length, and at its middle part about 3 in breadth; at this point irregular bony prominences and depressions could be felt. On measurement the scar was found to correspond to the upper part of the prerolandic convolution and the first and second frontal convolutions. On April 29th, 1891, Dr. Garibaldi operated. He first removed the whole of the bony cicatrix, resecting with the scalpel the cranial bones around the scar, and in this way making a breach in the skull of about 4 square centimetres in extent, and exposing the dura mater over the whole area. In the anterior part of the wound a swelling rather larger than a hazel nut, and containing serous fluid, was opened. There was a little hæmorrhage from the diploë and the dura mater on breaking down some adhesions; with this exception there was no complication. The operation was performed with the strictest

antiseptic precautions. Recovery took place without interruption; the wound healed almost entirely by second intention, as the skin flap, which consisted of old cicatrical tissue, partly sloughed. At the date of the report the cicatrix was fibrous and resistant. With regard to the fits the result was only moderately satisfactory. With the exception of a slight attack, which occurred the day after the operation, there were no further seizures until May 22nd, when general convulsions occurred twice. On the following day the patient complained of cramps in the lower limb, and on the night of June 5th another attack occurred, which was followed by headache. On June 30th and again on July 5th he had attacks during the night. On July 15th one took place during the day, and other attacks occurred at the end of the same month and at the beginning of August. The patient cannot, therefore, be considered cured, and there is little hope of much further improvement as time goes on.—*Brit. Med. Jour.*

THE TREATMENT OF VARICOLA.

According to Dr. Landerer, the extirpation or obliteration of varicose scrotal veins is apt to be followed by relapses. In one of his cases of recurrence he obtained an excellent result by letting the patient wear a hernia truss with movable pad, according to the method of Ravoth. One and a half years after application of the truss the varix had disappeared completely, and after wearing it for a year longer it was left off, and since eight years, there has been no return of the varicocele. An equally successful result was obtained in three other cases. The truss probably acts as an artificial substitute for the valves of the veins which have either completely disappeared in the varicosities or are in a rudimentary condition. This procedure is also applicable to varices of the lower extremities. For this purpose the author makes use of an apparatus consisting of a curved spring and a pad filled with water, which is made to press directly upon the saphena vein. He has employed this truss in eighty cases with very satisfactory results. Its application is much more agreeable to the patient than bandaging, and then it is much cheaper than an elastic stocking. Under the use of the apparatus a reduction in the size of the limb has been observed, but the treatment must be regarded as palliative rather than curative.—*Deut. Medizinal-Zeitung.*

MECHANISM OF FRACTURES IN THE DORSAL AND DORSO-LUMBAR REGION OF THE VERTEBRAL COLUMN.

In *L'Union Medicale*, July 2, 1891, Dr. J. Ménard gives the following conclusions:

(1) Indirect fractures are most common and are produced by forced flexion.

(2) There is first a sinking, then tearing, then breaking, the last often independent of the tearing.

(3) Simple sinking, constantly found in dorso-lumbar region, is not known in dorsal region.

(4) Breaking more frequent in dorsal; the tearing exists in both regions.

(5) Ordinary cause of dorso-lumbar fractures arise from falls upon the seat of lower limbs; more rarely from bodies pressing on the nape of the neck and top of back, with flexion of trunk.

(6) Dorsal fractures from falls on the nape of the neck or from flexion caused by pressure on nape of neck, and top of back—the trunk being vertical.

(7) With dorsal fractures, there are almost always fractures of the ribs, sometimes of the sternum.

(8) Compression of the cord generally caused by the posterior superior border of the inferior fragment of the body of the vertebra.

(9) The indication is to reduce and maintain reduction for a sufficient time.

(10) Trephining is seldom indicated and should be reserved for mixed fractures and crushings of the posterior arch.—*Univ. Med. Mag.*

AN OPERATION FOR TETANOID CONVULSIONS.

The *Centralblatt für klinische Medicin* refers to a case of Mr. T. R. Ronaldson's, recorded in the *Edinburgh Medical Journal*, in which a perfectly healthy child was attacked with tetanus on the eleventh day after birth. The birth had been a normal one, except that the child had a very thick umbilical cord. On examination, the stump was found discolored and foul-smelling. Symptoms of inflammation had not been present. Frequent washings with a corrosive-sublimate solution was carried out and everything was done to prevent a recurrence of the convulsions, but without avail. On the twenty-third day the author performed excision of the navel, with the result of the gradual diminution of the frequency of the attacks. By the end of the seventh week the convulsions had entirely disappeared

and the child was restored to perfect health. There was no micro-organisms found in the excised umbilical stump.

LAPAROTOMY FOR WOUNDS OF THE LIVER.

Broca (*Le Mercredi Medical*, 1891, No. 29) reports two cases of wound of the liver, each treated by surgical intervention, and each terminating fatally.

The first patient was seen six hours after the infliction of the stab wound. He exhibited the symptoms of large hæmorrhage. The wound was enlarged; the source of bleeding was found to be the liver; blood was flowing freely from the incision upon the anterior surface of this organ. An attempt to suture this wound proved futile, the threads tearing through. Thermo-cautery also failed to check the bleeding; an iodoform tampon was, however, entirely successful. An hour was consumed in the operation.

The patient perished two days later of abdominal septicæmia.

At the autopsy several other wounds were found, in some of which there had been bleeding after operation.

The second case was also a stab wound. The patient was seen four hours after the injury, and presented all the symptoms of intra-peritoneal hæmorrhage. The abdomen was opened and a non-penetrating and penetrating wound of the stomach were found. A wound three inches long was observed on the lower surface of the liver. By means of a silk suture this wound was closed and the bleeding ceased. The patient died in a few hours with symptoms of continued hæmorrhage.

At the autopsy it was found that the knife had passed completely through the liver, the wound of exit being located on the upper surface of this organ one-fifth of an inch behind the suspensory ligament. From this source sufficient blood flowed to entirely fill the pelvis.—*Amer. Jour. Med. Sci.*

AN IMPROVED METHOD OF GRAFTING ULCERS.

Dr. Gill in a letter to the *Lancet*, says that having had an exceptionally large number of chronic ulcers of the leg, which incapacitated the patients from work, and finally brought them into the infirmary, he tried the ordinary methods of grafting, but being disgusted with the very large number of total failures, he experienced, he undertook various experiments, and at last adopted the following plan, which he distinctly disclaims as his own, but which consists in adopting and combining the ideas of several people. The success he obtained with this method was so marked that he thinks a large number of practitioners at home and abroad (in India especially, where he found all ulcers very intractable under ordinary treatment) will welcome it. Even when the ulcer is deep, with hard thickened edges and extending all around the limb, the method applies. This is to cleanse the surface well for two or three days with boracic fomentations, and then (contrary to what he was taught) slightly abrade the granulations, just sufficient to cause oozing, and apply the graft directly to the abraded surface, where it is held in position by a small pile made of half-inch squares of green protective, four or five squares being placed one on the top of the other. A graft is thus applied to every square inch of surface. And now comes the most important thing of all, and which is an idea he received from a friend. This is to encircle the limb with a fold of carbolic gauze, which extends two or three inches above and below the ulcer, where it is attached to the sound skin by collodion. The ulcer is then thoroughly dredged with boracic powder through the gauze, and the whole is wrapped in a layer of wet boracic lint, which is kept thoroughly moist. As a rule, the dressing is not disturbed for three days, when the lint is removed, and the limb, well irrigated with boracic lotion, the grafts remaining perfectly secure under their heaps of protective, which again is kept in position by the gauze. The limb is then redusted with boracic powder, and done up in the wet lint, which is now changed daily. At the end of ten days the gauze and protective are removed, and each graft will be found as large as a sixpence, while those near the edges will have exercised a spermatic influence, and caused a rapid ingrowing of epthelium. Since adopting the above plan Dr. Gill says that he has never lost a single graft, though employed on most unfavorable surfaces—a very different result to the old way of covering the grafts with a large piece of protective which retained some exudations under it, and thus bathed the tender graft in a poisonous medium, with a result that 80 per cent. of them never "took."

IODINE WATER AND ARISTOL AS SURGICAL ANTISEPTICS.

Popoff speaks very highly of the antiseptic effects of irrigations with iodine water

(1 to 10,000), and consecutive powdering with aristol (pure or in a form of a 20 per cent. mixture with boracic acid) in cases of tuberculosis of joints (fungating arthritis, etc.) and bones, callous syphilitic ulcers, simple chronic ulcers, angina Ludovici, phlegmon, furunculosis, wounds of every description, etc.* The iodine lotion also gives excellent results in inveterate ozæna. In addition to its powerful antiseptic properties it has a decided astringent and hæmostatic action. Under its use luxuriant and profusely bleeding granulations rapidly assume a normal appearance, cease to bleed, etc. The iodine water likewise speedily checks parenchymatous hæmorrhage from any recent wounds.

CONCERNING THE TIME AND CAUSE OF THE EXTENSION OF GONORRHŒA TO THE PARS POSTERIOR URETHRÆ.

After an examination of fifty cases of first infection of gonorrhœa, Dr. Ignatz Heisler, (*Archiv. für Dermatologie und Syphilis*, 1891, 5 Heft.) concludes:

1st. That posterior urethritis appears much earlier than is usually taught and accepted by the best writers.

His statistics show that in twenty per cent. of the cases it appeared in the first week, in thirty-four per cent. in the second week, and in fourteen per cent. in the third week after the appearance of the discharge.

2d. Constitutional affections, especially syphilis, have little influence in hastening the occurrence of posterior urethritis, although the affection occurs more frequently in syphilitic subjects.

3d. Occupations which necessitate long-continued exertion play an important role in expediting affections of the deep urethra.

4th. The affection is equally prevalent whether injections are used or the treatment be confined to internal medication.

5th. The musculus compressor urethræ has no power to prevent the transference of the infective agent to the deep urethra.

6th. The gonorrhœal inflammation of the anterior urethra cannot be regarded as an affection of such typical course as is asserted by the majority of authors, *i. e.*, an inflammation starting in the fossa navicularis, reaching the bulb in three weeks; then, when the acme of intensity is attained, passing over to the posterior urethra. In the great majority of the cases, this happens during the first or second week without the direct transference of the gonorrhœal pus by means of catheters or sounds.

It must therefore be looked upon, not as a complication of anterior urethritis, but as a direct continuation of it.

SUTURING OF NERVES.

Th. Köllker (*Deutsch Chir.*, 189, Liefg. 246, Stuttgart, Ferd Enke, 1890). The discussion of the interesting question of primary union of divided nerves, as well as the processes of degeneration and regeneration, is entered into in connection with the subject of nerve suture and operations upon nerves. The author's researches, to be published later, show, contrary to Friedländer and Krause, degeneration of all of the fibres of the peripheral nerve stumps, the latter, according to Kölliker taking no active part in the process of regeneration, but simply serving as a guide for the newly-formed nerve fibres in their passage from the central nerve stump to the periphery. Immediate contact of the severed axis cylinder may possibly lead to immediate union of the same, but there is no indubitable evidence of this having occurred. Union by formation of a small amount of new-formation tissue, with the development of nerve fibres as demonstrated by the microscope, without degeneration of the distal ends of the nerves, according to K., has occurred.

In suturing nerves, Kölliker does not employ one method to the exclusion of the rest. In cases in which the ends can be brought together only after considerable force, the direct method is indicated; in cases in which there is no tension, the indirect plan is adopted. Silkworm gut, or catgut, is employed as a suture material. In cases in which there is a deficiency to the extent of 4 ctm., due to removal of a section of the nerve, he recommends stretching the nerve to fill the gap, and subsequent suturing. In cases of a more considerable gap, Vanlair's method of tubulization, or union by means of catgut loops, is preferable to nerve transplantation. In cases in which the central end of the injured nerve cannot be found, implantation of the distal end to a neighboring nerve is recommended. This method of "neurotization" whereby the distribution to a distant part is effected through the medium of a nerve trunk not originally destined for this purpose, promises to be a valuable aid in cases otherwise hopeless.

The Debility following Influenza is said to be greatly benefited by anacardium occidentale (cashew nut).

GYNÆCOLOGY.

NOTE ON THE VALUE OF IGNIPUNCTURE IN THE TREATMENT OF HYPERTROPHIED CERVIX UTERI.

Dr. Alexander Duke, writes in the *Lancet* that the length of time occupied by the usual routine treatment of a case of chronic hypertrophied cervix uteri can be considerably shortened by the judicious use of ignipuncture. The usual plans of treatment—viz., tampons of glycerine, copious syringing with very little hot water, painting cervix with Churchill's tincture of iodine, etc., —occupy a very considerable time, which prolonged treatment (unless the patient is able and willing to pay for) "is more honored in the breach than the observance." Superficial firing by caustics or smouldering pieces of carbon held in contact with cervix by forceps is not sufficient in well-marked cases of chronic hypertrophy to obtain the desired result within a reasonable time. Having observed the good effects on enlarged tonsils by the employment of ignipuncture, he has given it a trial, and can strongly recommend it as a useful adjunct in these cases. A thermo-cautery of small size and point (Paquelin's) will be found the best for the purpose, but those who do not possess this valuable instrument can obtain equally good results with a copper rod, sharp at the point, and with solid bulb about half an inch from the top, so as to retain the heat while the necessary number of punctures are made through a wooden or celluloid cylindrical speculum. This cautery can be heated with an ordinary spirit lamp till red-hot, held in the tissues for a few seconds, while each puncture, about a quarter of an inch, is made, and then withdrawn. There should be no bleeding observable if the operation has been properly performed, such being caused by the cautery being either too hot or too cold. His usual practice is to blow a little boric acid (with his vaginal insufflator) over the punctured surface, and make no examination for about a week, when the operation can be repeated if necessary. He has also found ignipuncture of great value in lacerations of the cervix when hardly bad enough to demand Emmet's operation. Little pain, if any, is produced unless the operator is unwise enough to allow the patient to observe the preliminaries.

A Faculty of Medicine is about to be established in Constantinople.

REMARKS ON A SERIES OF ONE HUNDRED LAPAROTOMIES.

Ten years ago to-day, Dr. Joseph Taber Johnson says, he performed his first laparotomy on a lady completely broken down, mentally and physically, on account of menstrual epilepsy. When he heard from her last, she was alive and doing well—not a "brilliant cure in sixteen days," but so much improved as to induce her to write that she and her family were very glad the operation had been done.

His next case occurred two years later; she also recovered. His next three cases died. None of them suffered from the four principal causes of death following laparotomy—shock, hæmorrhage, peritonitis, or sepsis. But still, he began at once to study over again his abdominal surgery, and in the hope of doing better work in future, took lessons from the best operators across the ocean, as well as in our own country. He saw Tait perform twenty-three abdominal sections. He studied the methods of Keith, in Edinburgh, Bantock and Thornton, in London. He had previously seen Sir Spencer Wells operate.

He saw operations under clouds of carbolic spray, and without spray. He saw every detail and variety of antiseptics used, and other operations, equally, if not more successful, where only "surgical cleanliness" was observed. He made many trips to New York, Philadelphia, and Baltimore upon invitation and toleration to study the methods of our most successful abdominal surgeons, in all witnessing and assisting, where he could, in at least two hundred laparotomies for a great variety of conditions.

After this increase of experience with men and methods, he had a run of 25 ovarian operations without a death; the twenty-sixth case died. Another run of fourteen cases without a death; the fifteenth died of tetanus the fourteenth day after the operation. Another run of thirty-three cases without a death—making a new series of seventy-three ovarian operations, with seventy-one recoveries and two deaths. The first series of five cases had three deaths.

In this report of 100 consecutive laparotomies, he only proposes to discuss, briefly, the value of surgical interference in some of the different groups of cases embraced in the accompanying table.

Laparotomy was done for the—

Removal of uterine appendages, ...	42	times with	3 deaths.
Ovarian tumors, . . .	37	"	2 "

Uterine fibroids, supra-vaginal hysterectomy, . .	12	"	4	"
Cæsarean section, . . .	1	"	1	"
Hydro-nephrosis (74 lbs),	1	"	1	"
Exploratory laparotomies,	3	"	0	"
Universal cancer, . . .	1	"	1	"
Ruptured tubal pregnancy (supposed), ...	1	"	1	"
Chronic peritonitis, . . .	1	"	0	"
Laparotomy for abdominal dropsy, ...	1	"	0	"

HYDRASTININ IN METRORRHAGIA.

Falk (*Centralblatt für Gynekologie*, No. 8, 1891.) has found that hydrastin is a heart poison, while hydrastinin is not. The latter has the advantage over hydrastin of producing considerable and regular vascular contraction. This conclusion was based upon the results obtained from treating twenty-eight cases of metrorrhagia from hyperplastic endometritis, congestive dysmenorrhœa and metrorrhagia accompanied by vertigo. In the former the metrorrhagia diminished. The chloride of hydrastinin, in a 10 per cent. solution in water, in doses of 5-10 cgr. (1–1½ gr.) is the preparation employed. It should be especially used before and during the time when hæmorrhage occurs.

OBSTETRICS.

HYPEREMESIS GRAVIDARUM, PTYALISM AND HYSTERIA.

Ahlfeld (*Centralbl. f. Gyn.*, No. 17, 1891). Kaltenbach in a recent paper has called attention to the frequency with which the hyperemesis of pregnancy occurs in hysterical patients and to the fact that the therapeutic measures which prove most successful in the treatment of hysterical manifestations have a favorable influence in the former affection. Yet he does not claim that the pernicious vomiting of pregnancy can be directly traced to hysteria. The author has met with several cases in which hysteria was the principal foundation of the uncontrollable vomiting. He regards both the hyperemesis and ptyalism of pregnancy as nothing more than an exaggeration of the reflex neurosis common in pregnancy in many women. His management of these cases is precisely the same as in hysteria uncomplicated with pregnancy. He enforces rest, forbids intercourse with friends and prescribes all mental excitement. His results he claims substantiate his doctrine.

Apropos of this question are the following remarks from the editorial columns of "Brit. Med. Journal" of May 30th, 1891:

This subject, of so deep interest to the practitioner, is at present occupying the attention of a large number of British and foreign obstetricians. Sixteen years ago there appeared in the journal the now celebrated paper by Dr. Copeman, which was read all over the globe, and gave his name to the "method" he advocated. Copeman's method simply means dilatation of the cervix with the finger. Undoubtedly it has proved of the highest service, whatever may be of the precise nature of its action. Dr Graily Hewitt, whose work on *Severe Vomiting during Pregnancy* appeared last year, traces the disorder to flexions, with inflammatory changes in the uterus. . . Other authorities refer the trouble to lesions of the cervix, and treat them with counterirritants. . . . There remains, unfortunately, the fact that in many cases nothing stops the vomiting save termination of the pregnancy. The induction of labor is not without risk; the practitioner is unwilling to resort to it when the vomiting has not lasted long, whilst later on the patient may be fatally enfeebled by constant sickness; hence the gravity of the entire question becomes self-evident. No wonder so much is written on hyperemesis graviadarum, but much more remains to be done before anything like a sound routine practice, suitable to others than hospital obstetricians of extremely specialized experience, is established to the benefit of humanity and the comfort of the practitioner.

PREGNANCY AND HEART DISEASE.

Dr. S. Remy (*Arch. de Tocol. et de Gynéc.*, August, 1891) publishes an instructive series of cases of death late in pregnancy from heart disease. The fatal event is sometimes sudden, taking place during work, dancing, or getting up. More often it follows asystolic phenomena. In the 15 cases collected by Dr. Remy the child was extracted, either by Cæsarean section or version, seven times; three were alive; in two of these three cases, if not in the third, death of the mother had been sudden. One fœtus extracted after "some delay" (precise length of time not being noted), was not quite pulseless when born. In cases of sudden death, the chance that the child may be living when the obstetrician acts promptly is considerable. When the mother has died from slow asphyxia due to asystolism, the child has

probably expired before its parent. In a case of this kind under Dr. Remy's own observation the child, promptly delivered by version, was beginning to macerate; it had evidently been dead for two days or more. The question of hastening delivery is grave. The actual birth of the child by premature delivery, when safely ended, leaves the woman for the time better off than before labor. Unfortunately premature labor in heart disease does not always improve the patient's condition. The cardiac and secondary lesions may be too serious to permit of more than the most temporary benefit. The labor itself places the patient for the time in extreme peril of fatal asystolism. Lastly, there remains a third fact, which may not be taken into account at the beginning of the case, when the induction of labor is contemplated. In lying-in patients with heart disease, severe cardio-pulmonary complications often set in on the third or fourth day after labor. Altogether it would appear best to induce abortion very early when cardiac disease, with grave complications, is present in a pregnant woman. Obstetricians may hesitate to take such a step, as they may wish to extract a viable child, and, as this involves some interval of time, the cardia symptoms may undergo some amelioration, or in some cases the child may die and be readily extracted. Hence it is hard to lay down a general rule; much must depend on the gravity of each individual case.—*Brit. Med. Jour.*

PREGNANCY AT THE AGE OF FIFTY-NINE.

Dr. E. Derasse (*Gazette Médicale de Liege*, October 1st, 1891) saw in his consulting room in August, 1889, a lady with a swelling of the abdomen. She was 59 years of age, and had been a widow for twenty years. The tumor was taken, by one of her medical attendants, for a uterine fibroid, and by another for a cyst. Arrangement had even been made for an operation. Dr. Derasse, on examining the tumor, which was uniform with the uterus, noticed a sensation as though something was moving inside it. On auscultation fœtal heart sounds could be heard; *ballotement* was also clear. The breasts were already well developed and heavy. After careful investigation of the case it transpired that the elderly patient had a young lover. On December 21st, 1889, she was delivered of a fine boy. She was then aged 59 years and 5 months, Dr. Derasse having succeeded in obtaining her birth certificate. She suckled her child well, and weaned it upon her sixtieth birthday. She stated that she had ceased to menstruate at 50 and she had a married daughter 40 years old. Dr. Derasse refers to the *Dictionnaire Encyclopédique* where several cases are recorded where mothers suckled their children at the age of 60, or even later.—*Brit. Med. Jour.*

PÆDIATRICS.

THE FREQUENCY OF INFANTILE CONVULSIONS.

Dr. G. L. Walton has found that out of 1,000 children, taken consecutively at random from all classes of society, 11.1 per cent. have been found to have a history of infantile convulsions. Among epileptics whose epilepsy did not begin in infancy, seven per cent. had infantile convulsions.

GONORRHŒAL STOMATITIS IN AN INFANT.

Professor Dohrn describes in the *Medicinische-chirurgische Rundschau* the case of a child, eight days old, which was brought to his clinic suffering with swollen jaws. A further examination showed the back of the infant's tongue and the roof of its mouth to be eroded and covered with a grayish-yellow exudation. An acute stage of purulent conjunctivitis being present, the mother was questioned as to the possibility of gonorrhœal infection, and her answers confirmed the suspicion of this being the source of the trouble. To be positive, however, a small portion of the diseased mucous membrane of the mouth was excised and submitted for microscopical examination, and numbers of gonococci were found. It was supposed that infection took place upon the abraded mucous membrane in the child's mouth, the mechanical injury having possibly been inflicted by the accoucheur.

ANTIPYRETICS IN CHILDHOOD.

R. Demme (*Jahr. f. Kinderhlkde*, Bd. xxxiii, H. 1 and 2) gives the results of experience with various antipyretics in the Jenner's Hospital in Bern. They were only given at all in cases in which the temperature exceeded 103° F. for several days; in milder cases cold applications or cold baths were employed (two baths daily at 77° to 82° F. for five or ten minutes). In articular rheumatism he gave sodic salicylate, or, if there was a tendency to vomiting and

diarrhœa, salol. Doses of salicylate, daily, 2 to 4 years, 7 to 15 grains; 5 to 10 years, 15 to 30 grains; 11 to 15 years, 37 to 45 grains—of salol, thrice daily, 2 to 4 years, 4 to 5 grains; 5 to 10 years, 8 to I2 grains; 11 to 15 years, 12 to 15 grains. In typhoid fever thallin sulf. was given every two hours; to a child 3 to 4 years old, ⅛ grain; 5 to 10 years, ⅓ grain; 11 to 15 years, ½ grain to ⅔ grain. In broncho-pneumonia with very high temperature (105° to 106°) he gives during the early stage hourly doses of antipin for two or three doses. Dose, 2 to 4 years, gr. iss to gr. iij; 5 to 10 years, gr. vij to xij; 11 to 15 years, gr. xij. to xv; larger doses are unnecessary, and may be dangerous. In the latter stage of broncho-pneumonia with hectic type of fever, quinine is superior to every other antipyretic. Doses, 2 to 4 years, gr. iij to vj; 5 to 10 years, gr. vij to viij; 11 to 15 years, gr. xij to xv. Antifebrin was found particularly useful in the high temperature of phthisis; like antipyrin, it sometimes caused a measly eruption. Doses, 2 to 4 years, gr. ⅔ to j; 5 to 10 years, gr. iss to gr. iij; 11 to 15 years, gr. iij to gr. ivss, once, twice, or thrice a day. Acetphenetidin was found a very satisfactory remedy, but had the disadvantage of causing sometimes copious sweats and frequently a measly eruption and cyanosis; it was best given in single large doses, 2 to 4 years, gr. iss to gr. iij; 5 to 10 years, gr. iij to vij; and 11 to 15 years, from gr. vij. A new remedy tested by Professor Demme was carbonyl-orthoamidphenol, or more shortly, oxycarbonil, an isomer of antifebrin which is excreted as oxycarbonil. As an antipyretic, it had to be given in larger doses than antifebrin, and its action was of very short duration, the temperature quickly rising again to the point at which it was before. Demme states that by repeating the dose every two hours, the temperature in typhoid may be kept down to 100° to 102° F.—*Brit. Med. Jour.*

TREATMENT OF DIPHTHERIA BY IRRIGATION OF SALICYLIC ACID.

In the *Bulletin Général de Thérapeutique* for September 15th, 1891, Dr. Parisot of Voyes publishes a paper in which he highly recommends irrigation of salicylic acid as a treatment for diphtheria. The former mortality of his cases was large (10 out of every 14); in a recent epidemic, when the new treatment was adopted, he had only five fatal cases out of every twenty-four, certainly a very satisfactory proportion for such a fatal disease. The formula which Dr. Parisot employs is as follows: Salicylic acid, one gramme water, 980 grammes; alcohol (90 per cent.), 20 grammes. The salicylic acid is dissolved in the alcohol, and the water added. The apparatus for irrigation is a fountain syringe, with the reservoir made of tin. This is hung against the wall over the patient. The rubber tubing, which is connected to a projecting nozzle at the lower part of the reservoir, ends in a small glass tube drawn out to a point. A spring catch on the tube controls the current of liquid. When the apparatus is filled with the solution the head of the child is held by an assistant, the tongue depressed, and the jet of fluid directed against the pharynx with sufficient force to detach and remove the false membranes. Several applications may be necessary to effect this, and if the membranes are not loose a little time must be allowed to elapse until this is the case. As regards the position of the head, Dr. Parisot recommends that this should be forward and a little downward. When the child is feeble, it should be supported upon the arm of the nurse with its face turned towards the floor, so as to prevent the liquid flowing back and being swallowed in large quantities. The amount of fluid used on each occasion must be learnt by experience. As a rule, three or four ounces each time is sufficient, and this should be practiced as frequently as possible. Dr. Parisot considers that salicylic acid has a destructive action upon diphtheritic formation. He showed by experiment that in distilled water the membrane simply became sodden and gradually disintegrated, this taking place very slowly, whilst in solutions of salicylic acid the membrane was rapidly dissolved; at the end of a few minutes only the meshes of network in which the cells had been supported were visible. The stronger the solution of salicylic acid the quicker and more complete was the destruction of the tissue. Dr. Parisot has further noted that when the diphtheritic membrane has been once removed by means of salicylic acid its reproduction was considerably slower and more imperfect, and therefore concludes that the acid has a favorable action upon the mucous membrane, which is rendered unsuitable for the growth of the pathogenic organism and the reproduction of the diphtheritic patches. —*Lancet.*

An hour-glass is made smallest in the middle to show the waist of time.

HYGIENE.

A POISONOUS THIMBLE.

Among the numberless causes of blood-poisoning through the skin, one which was lately recorded is worth noting on account of its evident simplicity and the ease of its prevention. In the case referred to the sufferer was a seamstress, and the mischief resulted from her using a dirty metal thimble marked with verdigris, a little of which appears to have entered a scratch on the thimble finger. We can well believe that this accident was not the first of its kind. Verdigris, it is true, is a mere metallic irritant, and not comparable in virulence to most living germs of disease. It is quite enough, notwithstanding, to excite local inflammation, which friction, contact with dyed cloth material, or the entrance of dirt in any form would quickly convert into a dangerous and general disorder. There is really no excuse for women who trust their fingers in these cheap and worse than useless articles. Steel thimbles are much safer and cost very little. Another variety also in common use is enamelled within, and is, if possible, even freer from objection. Let us not forget to add a caution that cuts or scratches on the hand should never be neglected by sewing women so long as dyes continue to be used in cloth manufacture.—*Lancet.*

TUBERCLE BACILLI IN THE AQUEOUS HUMOR OF CATTLE.

M. Mandereau, of Grenoble, having recently stated (see *British Medical Journal*, July 4th, 1891, p. 24) that tubercle bacilli could be seen in the aqueous humor of bovine animals suffering from tuberculosis before any other visible sign of the disease was present, MM. Leclinche and Greffier (*Sem Méd.*, July 1st, 1891) made a series of observations which, according to them, show the statement to be erroneous. They examined the eyes of twenty tuberculous oxen, and in no single instance could the tubercle bacillus be found in the aqueous humor, nor did the intra-peritoneal inoculation of that fluid in guinea-pigs in any case induce tnberculosis in the these animals.—*Brit. Med. Jour.*

If you are inclined to wonder at the number of maladies in the world, you should count the cooks.

MEDICAL CHEMISTRY.

HOW TO TEST DRINKING WATER FOR IMPURITIES.

Dr. Frederick J. Wulling, says in the *Pharmaceutical Era*: Sometimes the pharmacist is called upon, especially if his sign reads "chemist and druggist," to ascertain whether a sample of water is fit for drinking and domestic purposes or unfit for that end. It isn't a very difficult matter to apply a few tests for the simple determination of the figures or otherwise of a sample in question. A complete examination of the character of a sample of water is a very difficult problem and should be referred to a skilled chemist. The substances to be looked for primarily are organic matter, albumenoid matter, ammonia, nitrates and nitrites.

The nitrogen compounds are usually more abundant if animal matter is present; they of all other abnormal constituents render water the most unwholesome. Their presence, and of ammonia and of albumenoid substances, do not necessarily render water unfit for domestic purposes, but water containing them or either one usually becomes the breeding place of the germs of contagious diseases if they are around.

1. For organic matter, put a little of the sample into a beaker, add 2 or 3 drops of dilute sulphuric acid and color distinctly with a solution of permanganate of potassium. If much organic matter is present the color of the permanganate becomes discharged almost immediately; if less or very little, it takes longer to decolorize. If the color has not changed in 25 or 30 minutes it is safe to assume that organic matter was not present. This is a tolerably reliable test.

2. For nitrites, a little sulphuric acid added to the water forms nitrous acid if nitrites are present, which is easily detected by its power of liberating iodine from iodide of potassium. A little starch paste is mixed with a small quantity of a solution of potassium iodide, and the mixture added to the suspected water containing the sulphuric acid. If nitrites were present the nitrous acid formed liberates the iodine from the iodide, which turns blue with starch. This indirect method is a ready means for detecting the nitrites if present in not too small a quantity.

3. Nitrates are detected by converting into nitric acid, which turns morphia red. A portion of the water is evaporated to dryness, the residue treated with a drop of strong sulphuric acid (which makes nitric

acid of the nitrate) and a portion of morphine added. If nitrate was present the morphine gives red color.

4. For ammonia, Nessler's reagent is by far the best test. It may be made by dissolving 18 grains of oxide of potassium in a little water, adding solution of mercuric chloride until the red iodide of mercury first formed redissolves upon agitation. To this is added a solution of 50 grains of caustic potassa and distilled water to make 8 ounces.

This reagent will detect 0.00375 of a grain in a pint of water by giving a yellow color. A reddish color or precipitate forms with larger quantities of ammonia.

5. Albumenoid matter requires a more elaborated proceeding for its detection. If all of the above were found it is hardly necessary to go to the trouble of looking for albumenoids; the water would be unwholesome even if they were not present. If it is desired to test for them, nevertheless, Chapman and Waukly's test is the simplest to employ. If the water was found to contain ammonia, the latter must first be removed, as must also any urea that may be present. This is best done by distilling the water until it gives no reaction with Messler's reagent. Then add a strong solution of caustic potash and potassium permanganate and examine again for ammonia.

This test depends upon the fact that caustic potash and permanganate of potash cause animal matter while still in an albuminoid condition to unite with hydrogen to form ammonia.

It must not be understood that the tests just given are the only ones; on the contrary there are a vast number, all more or less useful, for the determination of the quality of a drinking water, but they are not all as practical and easily applied.

AN ARMY MEDICAL BOARD.

Will be in session in Chicago, Illinois, during February, 1892, for the examination of candidate for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before January 15, 1892, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

AMERICANS IN THE RIVIERA.

Dr. Wendt has been commissioned to visit the Riviera and the health resorts of the south of France in order to study and to report on the healthy conditions and the sanitary (or insanitary) arrangements, municipal and domestic, of the towns and hotels at such places as Cannes, Nice, Pau, Hyéres, Mentone, Monaco, San Remo, Alassio, Bordighera, Florence and Naples. He will find much to exercise his industry and acumen—much to blame, something to encourage, and many causes for warning to his countrymen. American visitors to the Continent are particularly liable to typhoid—of which the frequently recurring and sad examples are probably the main cause of this journalistic tour of inspection. Part of this special liability probably arises from their habit of drinking iced water. So long as, following the advice of Dr. Herman Weber, they confine themselves to natural mineral waters of recognized purity, they are safe. But these are not always at hand, and all do not yet understand that icing or aërating polluted water detracts nothing from its risks, and that even ice itself made from impure water is a source of danger. Where only "local drinking water" is to be had in the Riviera or anywhere on the Continent of Europe, it should always be first boiled and then filtered, as Dr. Gowers advises.—*British Medical Journal*, of Dec. 5th, 1891.

Dr. B. W. Richardson describes (*Asclepiad*, XXXI.) some old experiments in which he caused local anæsthesia by applying the positive pole of an electric battery over some narcotic. In many cases complete local anæsthesia was obtained; whilst the check experiments of applying the solutions and the current separately were followed by no anæsthesia.

Farbenfabriken vorm. Friedr. Bayer & Co.'s Pharmaceutical Specialties.

EUROPHEN.

This Product is formed by the action of iodine upon isobutylorthocresol. It possesses extraordinary value as a dressing in both simple and specific lesions. It has an agreeable odor and is, in all cases, a perfect substitute for iodoform. Europhen has been successfully employed by Drs. Petersen, Seifert, Szoldrski, Eichhoff and others, in the Dermatoses and many Inflammatory and Ulcerative Conditions, and has been given hypodermically in Syphilis. It is supplied in ounces.

PHENACETINE-BAYER.

As an Antipyretic, Analgesic, Anti-rheumatic and Anti-neuralgic, Phenacetine-Bayer is justly regarded as the safest and most effective of medicaments. In Acute, Inflammatory Fevers, Rheumatism, Neuralgia, Migraine, Bronchitis, Pertussis, Phthisis, and all affections in which fever, pain and restlessness, separately or together, are to be combated, it has an admirable influence. For Influenza (or *"la grippe"*), Phenacetine-Bayer with Salol is our best remedy. It is supplied in ounces, in pills and tablets of 2, 3, 4 and 5 grains; and also in pills combined with Salol or Caffeine.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

ŒDEMA AS A SYMPTOM OCCURRING IN MALIGNANT DISEASES—DIAGNOSIS BY LAVAGE—ACUTE GASTRITIS.

BY PROF. CHAS. G. STOCKTON, M. D.,
BUFFALO.
Professor of Practice, University of Buffalo; Attending Physician Buffalo General Hospital.

Gentlemen:—This man came to us last fall for an opinion as to his condition. At the time I found a tumor in the epigastrium and left hypochondriac region, extending from the ribs downward and forward to the umbilicus. By a thorough emptying of the bowel, it was proved that it did not depend upon a fæcal mass in the colon, it must lie either on or over the stomach and particularly on the lower border of the stomach. I decided that it depended upon a malignant neoplasm of the greater curvature of the stomach and probably of the omentum also. This tumor remains in the same position, it is larger, it is more superficial, it is more tender than it was, you can see it now as well as feel it. When he is lying down it is very apparent, running from the free border of the ribs in the left hypochondrium downward toward the umbilicus.

The man has had great pain, from which he still suffers. The treatment consisted in the administration of morphine to relieve pain, and the giving of peptonized milk. You remember that we found a marked diminution of urea, there being not more than half the normal quantity—a symptom which I consider of great importance in the diagnosis of malignant growths in the abdominal cavity and elsewhere.

Lately, this man has developed œdema, and his legs are now bandaged to support them. You can see the lines of the bandage upon his calves. His right leg is worse than the left. He had no œdema at all when he first came here. I presume he weighed twenty pounds more than he does now; although he has had rest, he has not exercised, he has been fed all he could eat, and particularly of milk and predigested foods. Œdema is an important symptom always, and we must seek its cause carefully. When there is general œdema it usually shows over the sternum and ribs. I do not find it here. There is nothing in the heart to explain his œdema. At first thought you would say that his œdema was to be explained by his anæmia and by the disturbance of the blood from the carcinomatous disease from which he suffers, and that may be quite enough to account for it. General œdema and very marked anasarca are part of the typical history of the later stages of malignant disease. You know how apt it is to occur in the later stages of phthisis. No matter where the neoplasm exists, the waxy appearance of the skin and the œdema especially localized to the feet is part of the general cachexia. In this case it so happens that in addition to the cancers and its accompanying anæmia, there is something wrong with the kidneys. The urine contains albumen which has increased in quantity, the urine is loaded with casts and desquamated epithelium. The patient has a chronic, diffuse nephritis, due either to the malignant disease directly, or it may be of an entirely different nature. Its rapid increase, however, concomitant with that in the tumor of the abdomen, makes me think that there is malignant disease of at least one kidney. But we must not be carried away in our reasoning by any preconceived idea. As an illustration of

the errors into which preconceived ideas lead us, I might relate the anecdote of a professor in a Southern medical college, into whose clinic a man came whom he thought he recognized. The professor turned to his class and said: "Now, gentlemen, look at this man; can you tell me what is the matter with him?" And, as no one replied, he continued, "He looks perfectly well to you, I suppose, but the moment I put my eyes on this man I knew he was a deaf mute; he can neither hear nor speak." At this point the man spoke up and said: "I beg your pardon, boss, but it is my brother who is a deaf mute; he sent me in to see if you were ready for him."

It is very easy to get a preconceived idea about a case; therefore, before you make up your mind that a patient has a certain condition you must demonstrate it without jumping at conclusions. I might very easily have explained this œdema to you on the ground of the blood dyscrasia due to the malignant disease, and we might have neglected his kidney lesion, but by carefully diagnosing and then attending to it, we may be able to prolong his life.

I shall continue with the morphine to relieve this man's pain, the peptonized milk to support him. His bowels shall be kept open and his skin stimulated. There will be no medication directed especially against the Bright's disease.

DIAGNOSIS BY LAVAGE.

This patient has been under treatment for what has been supposed to be gastric ulcer. He is a woodsman, aged 45, who has been obliged to discontinue his work on account of vomiting, pain in the stomach, fermentation, with the formation of gas and intestinal indigestion in addition to the condition in the stomach. He has been on a milk diet, with salol and pancreatine given after meals, the former to prevent fermentation, the latter to aid in the digestion of the milk. At present he is without pain, he has no vomiting and he feels very well. Without discussing in detail the reasons for the diagnosis of gastric ulcer, I would say that of late we have been led to reconsider the question. In the first place, 75 per cent. of all cases of gastric ulcer occur in women, and they generally occur early in life, whereas this man is over 40. It is rare for an ulcer to occur in a man engaged in hardy out-door work. Again, his vomiting has been noticed to occur particularly in the morning, after breakfast, while in ulcer it occurs typically with equal frequency after every meal. If he would not empty his stomach by vomiting immediately he suffered pain. That is like gastric ulcer. The pain was rather localized, and at a point where the pain of gastric ulcer is usually felt, midway between the ensiform cartilage and the umbilicus, and a little to the right of the median line. There is local tenderness at this point also, but although I do not find a general tenderness, I can make out several tender points. The pain of gastric ulcer is usually made worse by eating at any time, but, on close questioning, I find that sometimes our patient can eat without any disturbance whatever. His vomiting, he says, has been sour, a symptom which is characteristic of gastric ulcer, in which, according to my experience, there is always an excess of hydrochloric acid. I must accept, however, the statement of other observers, who assert that ulcer is not always accompanied with an excess of hydrochloric acid. The contents of his stomach have not been examined, for the presence of this acid and the sourness complained of may have been due to acids of fermentation, acetic, lactic, etc.

This case is a little perplexing, and while strongly suggestive, it is not typical of gastric ulcer. Let us see if it can be explained on another hypothesis. There is a neurosis of the stomach, characterized by the excessive secretion of hydrochloric acid and by gastralgia. I believe that gastric ulcer depends upon imperfect innervation of a certain part of the stomach in connection with the same acid neurosis, and that owing to the intensity of the hydrochloric acid and the stomach ferments, this portion of the stomach is digested. But there may be the same group of symptoms of gastralgia, vomiting, localized tenderness and excess of hydrochloric acid without the actual existence of the ulcer. When there is no ulcer, but simply the acid neurosis, there may be occasionally a meal taken without any pain whatever, and then the next meal will cause pain. Depending upon that one point, I might dismiss this as a case of gastric acid neurosis, but the diagnosis can only be made after careful study, and we must not go so fast, for men and women have died of gastric ulcer without having had pain,

vomiting or any other recognized symptom, and yet the ulcer has been found *post mortem.*

I propose, therefore, to empty this man's stomach through the tube and examine its contents, first, to see if there is an excess of hydrchloric acid; secondly, to ascertain the digestive strength. Three or four hours ago he had a meal of bread and butter, meat, egg, and some milk. The egg and milk I did not intend him to have. Now we ought to find the stomach contents a pulpy mass, showing the meat decolorized, the starch dissolved and hydrated; the butter ought not to appear as distinct particles of floating fat, but the capsules of the fat cells should have been broken up and the contents should have passed in large part into the intestine.

Ordinarily, for the purpose of emptying the stomach, it is best to have a continuous tube, for joints are apt to interrupt the outward flow of solid substances. It should be four or five feet long and an inch and a half in circumference. It should be flexible enough to be introduced into the œsophagus without causing damage, but not too soft. It should have two openings into the stomach, one at the end as large as the lumen of the tube, the other on the side, so as to render accidental plugging of the tube less likely to happen, but this opening should be less than an inch from the end, as otherwise gas entering it from the stomach might spoil the siphonage. The stomach tube is usually passed twenty two (22) inches from the teeth. Sometimes, owing to dilatation of the stomach, it is necessary to insert the tube to a depth of from twenty-five to twenty-eight inches, and the distance depends somewhat on the height of of the body, but there is unusual uniformity in the rule that the tube acts best when passed to a depth of twenty-two inches.

I will now introduce the tube, directing the patient to give most of his attention to taking long breaths, in order to distract his attention from the tube. It is a good plan to have the patient vomit some of the gastric contents undiluted, but often, as in this case, it is necessary to put in a little hot water, so as to fill the siphon, and it is well to make sure that the water is not too hot.

After some manipulation of the tube, I remove part of the stomach contents, showing lumps of undigested meat, oil floating on the surface of the fluid, and starchy food in masses. I see nothing in the way of milk or milk curd. The digestive strength of the stomach is below par, and as there is so much solid matter, we will abandon the attempt to empty the stomach and withdraw the tube. Applying the phloro-glucin-vanillin test, there is a fair reaction to hydrochloric acid, but no excess. The chloride of iron and carbolic acid test shows the absence of lactic acid.

Considering this man's age and occupation, the history of pain and vomiting, in the morning particularly, and not always following meals, the absence of an excess of hydrochloric acid, the slowness in the digestion of meat and albumen of all kinds, all of which things are contrary to the idea of gastric ulcer, it seems to me that this man has not that disease. Furthermore, he has not that form of neurosis of the acid type which I have described to you. He has a form of indigestion in which the ferments are not of sufficient strength, and he is lacking in the power to digest albumen. This we can prove by filtering part of the gastric contents and adding a small amount of egg albumen and noting the time necessary for digestion at the ordinary temperature. The time should be two or three hours, if it be five or six hours the stomach is weak, and if the egg remains for twenty-four hours without change, the peptic strength is practically nothing.

The origin of this man's trouble was probably from taking too large amounts of food when he was tired and unable to digest it. The pain from which he has suffered is an ordinary gastralgia. How to account for the local tenderness I do not know, unless there has has been some local injury to the stomach by a hard fragment of bone which he has swallowed.

I am inclined to think that by giving a milk diet, with long intervals between the meals, he will improve. The milk should be given digested, if necessary, either by peptonising it or by giving pancreatine with it, as is now being done. If he had an excess of hydrochloric acid, either with or without ulcer, I would give frequent meals to keep the acid busy digesting food rather than acting on the stomach wall. The treatment of the acid condition by complete rest of the stomach and rectal nutrition may also be carried out, for if we give no food the acid will not be secreted. But one extreme or the other of treatment must be carried out.

ACUTE GASTRITIS.

There is little in the history of this case that needs to be repeated. A man of forty-three, in good health, save that he had been drinking, and while somewhat under the influence of alcohol, he went into a barber shop and was there given to drink what purported to be bay-rum, but which was in fact a mixture of bay-rum and ammonia. How much of this he drank he does not know, but probably three or four ounces. He fell down and lost consciousness, and then the next thing he remembers is that he was in the hospital. He was treated at once by the accident hospital surgeons; his stomach was emptied and he was given demulcents. He was brought here unconscious, but he very soon revived and the stomach was found to be acutely inflamed. This is an instance of a rather rare disease, according to my classification—acute gastritis. He had the usually profound symptoms, which subsided under treatment, but they were followed by symptoms of sub-acute gastritis, which is very apt to follow the acute. The sub-acute gastritis was accompanied by such symptoms as vomiting, tenderness on pressure, general malaise, slight rise of temperature, a continued albuminuria, which was present during the acute gastritis, and wakefulness. The sub-acute gastritis might possibly have been, to a certain extent, due to the alcoholic habit. He has been drinking right along since Christmas, and probably his nervousness and vomiting have been due in part to that fact. He has made a good convalescence on demulcents and rectal nourishment till he was able to take food by the mouth, when he was given peptonized milk in small quantities.

The symptoms of acute gastritis, properly so called, are pain, tenderness, vomiting, and the vomit containing mucus and sometimes blood and shreds of mucous membrane, generally high fever, usually very marked cerebral disturbances and often albuminuria, sometimes casts and blood appearing in the urine as well as albumen; sometimes hæmorrhages and melæna or bloody discharges, showing the presence of changed blood in the stools.

I am not going to quarrel with those writers who call what is described here as sub-acute gastritis, acute gastritis. It is simply a question of terms. But remember, when you have an acute gastritis due to poisoning or the swallowing of hot fluids, you have a serious disease to deal with. That which is ordinarily called acute gastritis, I think is properly called sub-acute gastritis, since its symptoms are much milder. The treatment by demulcents is very important. A person may be given oil when he is vomiting to make the vomiting easier and to help empty the stomach. Pure salad oil may be given; after that mucilaginous drinks, like acacia water or slippery elm tea, or albumen in water should be administered until the stomach is quieted down. Then the patient should be given bismuth stirred in water, not the dry powder. It cannot be dissolved, but it can be suspended in mucilage water better than in clear water. It acts as a dressing to the inflamed mucous membrane. With the bismuth I think it is very useful to give cerium oxalate, and it is also advisable to give such patients morphine hypodermically.

COMMUNICATIONS.

THE MEDICAL TREATMENT OF APPENDICITIS, WITH A REPORT OF FIVE CASES ENDING IN RECOVERY.*

BY A. B KIRKPATRICK, M. D.,
PHILADELPHIA.

The diagnosis, symptomatology, and pathology of diseases in the region of the cæcum have been so recently and ably given by Drs. Price and Morton, members of the society, that it would be useless for me to go over the ground again and attempt to add anything new on the subject. Surgery has made such marvellous advancement and accomplished such brilliant results in the last decade, that the medical treatment of certain diseases appears, at least for the time being, to be eclipsed. I am led to believe, from my limited experience, that some of our younger surgeons are too ready to perform abdominal section before they have exhausted the medical armamentarium, which, though perhaps somewhat slower, *may* be surer and subject the patient to less risk.

I think the surgeon in consultation with the physician will be able to determine and select the cases for operation, if they are so fortunate as to see them in

* Read before the Philadelphia County Medical Society, December 9th, 1891.

their incipiency, but in many of these cases the physician is called in late, and the surgeon later—too late in some cases.

We are all more or less infatuated with the wonderful results of present surgery, because, I think, it is something tangible. We make our diagnosis of appendicitis, open the abdomen and remove the diseased organ. There is the ocular proof of our skill in diagnosis and operation. In medical treatment our evidence, if we can produce any, is not so conclusive. It is of a more circumstantial character.

No one of the same experience feels more deeply than I do the debt of gratitude we owe to aggressive surgeons, and no one, I think, takes the knife with more satisfaction, but I must always be *certain* that it is the *only* or safest method for the patient.

In the five cases that I wish to report, I demonstrated within twenty-four hours —in four of them at least—that an operation was not necessary, and all the five recovered without section. You may infer that they were all mild or benign. Three of them were, because seen early and treated vigorously.

Perhaps the title of my paper is not broad enough to cover it, but I wish to include in the medical treatment of typhlitis everything short of surgical operations, for I rely as much, or more, on mechanical measures as on internal medication. I wish to report what I consider as the most critical case first, though it was my third in regard to date. The first case dates from March, 1889.

In four of the cases other physicians had been in attendance, or saw the patient with me in consultation. Two of the cases came to my notice late in the disease, and to make the history complete, I shall be obliged to read parts of several letters which were kindly written to me by the physicians who first had the cases in charge.

For the previous history of the first case, I am indebted to the kindness of Dr. Edwin B. Wheeler, who wrote me the following letter two months after treating the case:

"Was called to see Master A., thirteen years old, Thursday, April 2, 1890. He had been constipated a day or two, evidence conflicting as to the condition of the bowels previous to that time. There had been no diarrhœa, however. I first thought it a case of typhoid fever, as the father had just recovered from that disease. I ordered a powder of calomel, but no action. Then gave one bottle of citrate of magnesia in half-bottle doses, with no result. The pain and tenderness in inguinal region increasing. Some tympanites. Gave injection of tepid, soapy water, with a few drops of turpentine without any result. On Friday I gave drachm doses of Rochelle salts in one-third of a glass of water every hour for four doses, and tincture of hyoscyamus. There was no result so far as any action of the bowels was concerned. The vomiting was increasing and the tenderness covering a larger area. During this time it had become apparent that we had to deal with an obstructed bowel due either to intussusception typhlitis or perityphlitis.

"Injections on Saturday morning were not retained. Passes up a catheter, but still injection was not retained. Gave morphine in small doses. Saturday p. m. Dr. J. H. Dripps saw the case with me. We agreed as to the case, but were both on the fence as to the advisability of section. We then called in Dr. Noble, of the Kensington Hospital, Saturday, 6 p. m. After talking over the case, we concluded that the boy's best chance was to have the belly opened and the obstruction removed. We ordered a room cleaned and agreed to see the case the next day.

"At 9 a. m., Sunday, April 6th, we (Drs. Dripps, Noble and myself) met and concluded that the boy's chance would be slight if we operated in such unsanitary quarters, with such nursing as the father and mother could give. The parents agreeing, we wrote to the Pennsylvania Hospital, asking them to take the case, the father to let me know the result of his errand. We separated with the understanding that if the hospital refused to admit him, we would operate, Dr. Noble saying he would hold himself in readiness until 2 p. m.

'About 11 a. m., the father informed me that the hospital authorities would send for the case as soon as I desired. I sent him back to the hospital with word to send for the case immediately. Somewhere about 3 p. m. the father informed me that he had been down town, but did not go to the hospital. He had stopped to see the boy's aunt, who said he should not go to the hospital. Whereupon I dismissed the case, refusing to have anything further to do with it. The case has certainly resulted very fortunately in your hands, and I am truly pleased, etc."

I will not go fully into the diagnosis of this case, for I was perfectly satisfied when I learned from the father who had consulted in the case.

"I was called in to the case at 10 p. m., Sunday, April 6th. The symptoms all indicated complete obstruction of the bowel and collapse. He had vomited first on Wednesday. The temperature was 96½°; pulse indistinct at wrist; heart was 140 per minute, and he was in a cold perspiration; respiration 40. Abdomen exceedingly tympanitic and bladder much distended. There was stercoraceous vomiting, and nothing had been kept on the stomach for days. I at once gave a hypodermic of morphine, atropine and strychnine, and then emptied the bladder by a catheter, and about sixteen ounces of water passed. The patient was apparently moribund, but revived somewhat after the hypodermic injection, and though I feared he would die while giving it, but I knew there was nothing to lose and thought there might be a slight chance for life if the obstruction could be removed, so I had him supported in the knee-chest position and injected a pint of warm liquid containing

castor oil, turpentine, whiskey and Epsom salts. This was about 11 p. m.

This was kept in the bowel for half an hour by a compress, held in position by the hand, then he was allowed to lie down on the right side. Within an hour there was copious evacuation of liquid with scybalous masses The injection was repeated at 12 o'clock, and another free movement resulted. These greatly relieved the tympany and pain. We then began to give turpentine and whiskey by the mouth once in two hours, and also a drachm of Epsom salts in hot water once in two hours alternately. Only the first dose of salts was rejected. The whiskey and turpentine were retained. These were regularly administered through the night I left the patient at 1 a. m. asleep, and he had become much more comfortable.

"On returning in the morning, I found there had been several more movements, and the bladder had been emptied naturally. The tumor over the right iliac fossa had nearly disappeared, and the pain and tenderness were much less. The temperature was normal. The tongue and sordes on teeth indicated typhoid fever. There were five movements of the bowels within twenty-four hours after the enema, and not less than three to six any day after for two weeks. The temperature gradually rose to 102°, and the evening temperature was about that for a week, when it gradually declined, but did not become normal till the 29th, or three weeks from the time I first saw the case. The stools had quite the appearance of typhoid, as did the tongue, and there was a suspicious eruption on the chest and abdomen. After the obstruction was removed the case was treated as a simple case of typhoid fever. He had two grains of quinine and one-thirtieth of a grain of strychnine three times a day, with nitro-muriatic acid, pepsin and bismuth every four hours, and paregoric when needed to control the bowels, and a liquid diet throughout.

"At noon, the fourteenth day after I first saw him, after some pain and flatus, he passed a slough from the bowel, which, in the recent state, was elliptical and two and a half inches the long diameter. There seemed to be some pain and tendency to collapse, so he got another hypodermic and free stimulation. There was also a rise of 2° in temperature. He rallied the next day, and made a rapid and complete recovery.

"On May 6th, which was just a month from the time I first saw him, he sat up and took solid food.

"He is a strong, healthy boy and now drives for me."

I watched the case very closely throughout, and feel certain that the intussusception, or typhlitis, or perityphlitis, was followed by a clear case of typhoid fever. I am by no means so clear in regard to the pathological condition in the region of the cæcum and shall greatly appreciate the views of the members of the society on that point.

"The second case, Mr. M. K., who is a prominent and very active literary man in this city, dates from March 24, 1889.

"The patient gave me a very intelligent history of his case, which was that there had been a gradual decrease in the evacuations for several weeks, with a great deal of distention and discomfort of abdomen, and finally obstinate constipation followed. When I first saw him there had been no movement for several days.

"He had a tumor and localized pain in the right iliac fossa. Temperature 103½°. Pulse 120. Coated tongue, etc.

"He was given a hypodermic of morphine and atropine for the pain, which gradually spread over the abdomen as the gas accumulated. Two large doses of castor oil and turpentine were taken without any action. He took calomel, soda and ipecac powders for twelve hours, followed by Hunyadi water, but still there was no movement of the bowels. We then resorted to the enemata of turpentine, laudanum, castor oil, Epsom salts, and hot water, given in the knee-chest position. These moved the bowels freely and relieved the pain and distention. Turpentine stupes were also used freely.

"There was a double inguinal hernia in this case, and to satisfy ourselves that there was no strangulation of the gut. Dr. W. W. Keen was called in consultation, and pronounced the case free from any such complication and confirmed the diagnosis of appendicitis. He suggested pills of colocynth comp. and opium.

"The patient made a good recovery, and for several weeks took pills of aloin, strychnine, belladonna, cascara and physostigma to relieve the atonic condition of the bowel, and an occasional dose of Hunyadi, as he was rather stout and full-blooded.

"In July, or four months later, this same patient had a recurrence of the trouble while at the seashore, which began, possibly, with a slight tendency to constipation early, but the first the patient complained of was a severe serous diarrhœa with high temperature—104°. Pulse 128 (normal 58). Severe pain in the ileo-cæcal region. This attack began before I took up my summer practice at Cape May Point, and Dr. F. E. Stewart, of Wilmington, was called in.

"He made the diagnosis of colliquative diarrhœa, and gave acetate of copper and morphine to check it, and aconite for the fever, but nothing seemed to have any permanent control over the bowels.

Right here in this case, which was my first patient, but his second attack of appendicitis, I learned a very valuable lesson. Here was an obstructed bowel, and nature was trying, by pouring out a very excessive liquid secretion, to flush out the obstruction or foreign matter.

I simply took the cue from nature, and with small, frequently repeated doses of calomel, ipecac and soda, followed by salines, accomplished the object, and in less than six hours had the satisfaction of seeing the tumor, which had been in the region of the cæcum, deposited in a commode, which the black, very offensive mass nearly filled. In this attack we used hypodermic injections of morphine for pain, and pilocarpine for the high fever and dry skin and tendency of cerebral congestion, as the kidneys were not acting at all freely. There was no vomiting after the first hypodermic, and the patient began at once to take iced

champagne and Apollinaris, and soon was able to take milk and other liquid food.

In this case no resort was had to rectal enemata, as the bowels were thoroughly cleared out within six hours after the time I first saw the patient, and in three or four days he was attending to his regular business. He took the aperient, tonic pills for several months, and was requested to use Hunyadi water freely, and rectal injections, if the symptoms occurred again. He has had no recurrent attacks and no constipation since.

The fourth case, Miss S., occurred at Cape May Point, and was first seen and treated by Dr. F. E. Stewart, Wednesday, August 25, 1891. I wished to speak of this case at the special meeting, September 28th, when Dr. Morton read his interesting paper on "The Surgical Treatment of Appendicitis," and wired Dr. Stewart for his diagnosis, and he sent me the following telegram: "Case was obscure. Called Dr. David Stewart in consultation. He said 'appendicitis.'" I am indebted to Dr. F. E. Stewart for kindly furnishing me the history of this case, which I quote from his letter:

"In the case of Miss S., there were pain and tenderness over the abdomen, which, as the case developed, became marked in or over the right iliac fossa. Instead of dorsal decubitus, the patient sat in a chair with her thighs flexed on the abdomen, and could not lie down until relieved by treatment. There was fever; temperature 102°. There was constipation, nausea, and, if I remember correctly, some vomiting, but the latter was not a marked symptom of the case. I did not discover a tumor on abdominal palpation or vaginal touch, but Dr. David Stewart, who saw the case with me on the second day, called my attention to what appeared to be a doughy mass on the right side of the body on examination *per rectum*. I must confess that I would not have discovered said mass except my attention had been called particularly to it, or, in other words, I might have had a suspicion of its existence, but it required a finger of more education than mine in feeling for tumors of this nature to make a positive diagnosis.

"The treatment suggested consisted of hot turpentine stupes, opium and iodide of mercury. Under this she seemed to improve.

"From the beginning I recognized the gravity of the case. I advised her to go to the city at once, as proper nursing was out of the question, situated as she was at the Point. Furthermore, I told her if she got worse an operation might become necessary, and then it would be too late to remove her.

"I first saw the case on Monday, August 31st, at 6.30 p. m., and found her extremely weak and nervous from the trip from Cape May Point. The temperature was 103½°, pulse 120, abdomen tense, tympanitic and extremely sensitive. I found a large tumor in the region of the ileo-cæcal valve, intense pain and nausea. There was extreme tenderness over the tumor and abdomen generally, indicating a good deal of general peritonitis.

"Miss S. was brought to the city by her sister-in-law, and they went into a house where the furniture had just been piled in. There was not even a bed up or any convenience for heating water, so in regard to nursing and environment she did not improve her condition. When I arrived she was on a bed that had been hastily put up.

"The sister-in-law, who acted as nurse, got hot water for stupe and enema, and the patient had the same treatment, practically, as the boy—the first case reported—except that the nurse gave the enemata, who proved very intelligent and efficient.

"When I called next morning, I found the bowels had moved freely several times, and though the patient had had a restless night, she had slept some. The pain and distention were nearly gone and the temperature had fallen to 101°. By Wednesday, September 2d, the temperature was normal and the pain was entirely gone. She began sitting up Thursday, without my knowledge, and the next Wednesday she went back to the Point. I believe she had a slight recurrence of the pain, inflammation and constipation the week after she got home, but they were controlled by injections, stupes and opium suppositories.

"She has enjoyed good health since."

The other two cases of typhlitis, which occurred in my practice within the last year, were quite similar in regard to symptoms and treatment to the others that I have reported in detail, and as I relied only on myself for the diagnosis and treatment, I will not weary you with a repetition of them. I have not aimed to give the latest and most approved treatment from the text-books of the day, but what seemed to me to be indicated and necessary in the emergencies of these cases, when I dared not waste a moment in temporizing or experimenting. It appears to me a serious loss of time to depend solely on external applications to the abdomen and protiodide of mercury with belladonna and opium internally, when we have to deal with a bowel obstructed by hardened accumulation of fæces. I believe most cases of obstruction of the bowel, if not due to intussusception or strangulated hernia, are due to the absence of the natural secretion caused by the localized typhlitis, which, if not soon relieved, becomes a perityphlitis, and then more or less general peritonitis must result. The rational method seems to me to be: (1) To relieve the pain by hypodermic injections. (2) To remove the cause or obstruction by causing, if necessary, pathological or excessive secretion, by giving some saline, which I believe is the best antiphlogistic for the inflamed bowel. (3) To soften the hardened fæcal accumulation from below with

enemata, solution of Epsom salts in water as hot as can be comfortably borne, to which I add turpentine and oil. The knee-chest position, with copious enema, favors the distention of the colon up to the seat of the disease.

I have found by experience that the enema to be effective must be given in this position, and that it must remain in the bowel for some time, and in several of my cases it was necessary to repeat the operation three or four times. This plan of treatment has been successful in six cases, which are all that I have treated; but I fully realize that it may fail in the seventh.

I think it is truly in meetings like this that surgeons are broadened medically and physicians surgically—if I may be allowed the phrase. Doctors are only human, as we hear it said of ministers, and as such they are prone to do what they prefer, whether it be surgical or medical, and naturally they do best what they like to do and do oftenest.—*For discussion, see Society Reports.*

ABSCESS OF THE ANTERIOR VAGINAL WALL.*

HENRY R. SMITH, M. D.,
DETROIT, TEXAS.

I was consulted August 11, 1891, by Mrs. G.——, aged twenty-one, married two years. She has never been pregnant, looks swarthy, is weak and gets easily out of breath. She dates her present trouble back six years. First menstruated at twelve years of age; has not menstruated during the past four years; has constant pain in the lower part of the abdomen; has to get up three or four times during the night to urinate. She has a leucorrhœa and some pus from the vagina; temperature 101°; pulse weak, and has not been able to do her housework for some time past.

On digital examination I find a tumor-like body situated in the anterior vaginal wall, just inside the vulva, the size of an orange, hard to the touch, and no fluctuation. The exploring needle reveals pus. A free incision was made into the tumor, and a pint and a half of foul-smelling pus evacuated. The cavity, which measured four inches, was thoroughly curetted, and then irrigated with bichloride of mercury solution 1-2000, and also peroxide of hydrogen. The patient was seen three days later; some pus escaping. A drainage tube was introduced, and the cavity ordered to be washed out twice daily with bichloride solution. No fever.

On the tenth day after operation, patient was doing well. No cystitis; patient sleeps well at night; treatment continued.

Fifteenth day, menses returned, and not painful. Drainage tube removed, and cavity injected with tincture iodine. Twenty-first day, some pus discharging; drainage tube re-introduced; cavity ordered to be washed out twice daily with bichloride solution. Patient looks well; has gained twelve pounds in weight. Thirty-first day, no pus; drainage tube removed, and cavity injected with nitrate of silver.

Sixth week, there was no discharge; menses regular and not painful; no cystitis; abscess cavity retracted. Patient is now doing the cooking for twelve cotton pickers, and considers herself well. Case discharged.

I wish to say, in conclusion, that Mrs. G.—— has been taking medicine from doctors and using patent medicines for the past six years. The lower part of her abdomen is a solid scar from blisters.

* Read before the North Texas Medical Association, December, 1891.

THE SIMPLE EXTRACTION OF CATARACT.*

EDWARD JACKSON, M. D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC AND SURGEON TO WILLS EYE HOSPITAL.

The old flap operation for the extraction of cataract, when it was successful, was one of the brilliant triumphs of operative surgery. The trouble with it in the old time, before the day of Graefe, was, that it was successful in only a minority of cases. The real achievement of the last few years with reference to it has been the increasing of the percentage and the perfection of its successes, until they have surpassed anything achieved by other operations for cataract extraction. This has been

*Read before the Philadelphia County Medical Society, October 28th, 1891.

brought about by collateral advances in medicine and surgery, that have given us an understanding of sepsis and asepsis, of the myotic power of eserine and its allies, and of the anæsthetic and other powers of cocaine.

My purpose in this paper is to discuss the operation of "simple extraction" as I practice it, with the reasons for choosing certain procedures rather than others, and some comparison of the results of the method with modified linear extraction, or modified Graefe method, which it has largely replaced. I used the term "simple extraction," because it is one commonly employed to designate the operation in question, and not to give the idea that cataract extraction was at all a minor or trifling operation. I think though that the term is strictly applicable, for the operation is distinctly simplified in certain directions. And in that it is more simple it conforms with the general tendency of surgical advance at the present time, which is toward the omission of various procedures that were formerly believed necessary, and the concentration of our attention on what is really essential, that it may be done in the best possible manner.

The corneal section is made upward, mainly because it seems to me that the wound in this position is much better protected beneath the closed lids from either infection or the relative displacement of its lips than the downward section can be. It is made in the clear cornea, sometimes as close as it can be to the limbus without encroaching on it. It is parallel to the corneal margin, the plane of the knife making it being parallel to the plane of the periphery of the iris. It is made to include nearly, and sometimes quite, half of the circumference of the circle of which it is a part. The exact position of the section and its length are determined by the size of the cornea and the supposed size of the lens. The plane of the section should be well in front of the iris, for the risk of prolapse of the iris is thereby greatly lessened, yet the incision must be long enough to permit the escape of the lens. The section is made with the knife described by me in the *American Journal of the Medical Sciences* for March, 1888, for the reasons there given, that it combines to to a large extent the manageableness of the Graefe knife with the smooth incision of the Beers knife. Usually the incision is almost completed by the forward thrust the cutting edge being carried by it out of the anterior chamber, and the remaining bridge of corneal tissue severed as the knife is withdrawn.

The capsulotomy is made with the point of the knife used in making the corneal section, and is about in the plane of the corneal section, as the lens lies against the cornea after the escape of the aqueous, I have in a few cases opened the capsule before completing the corneal section, as the point of the knife was carried across from the puncture to the counter-puncture. This was done in the fear that after the escape of the aqueous the pupil would contract so that it would be difficult or impossible to make a sufficient laceration of the capsule without wounding the iris with the knife-point. Such a manœuvre, however, required a slight change in the direction of movement, and prolonged a little one of the most critical periods of the operation. It was given up on finding that a sufficient opening in the capsule can always be made through the pupil after the completion of the corneal section. The opening that is necessary to make in the capsule is really quite small, a slit 4 or 5 mm. long is quite sufficient, probably because, when the solution in the continuity of the capsule is once started it extends quite readily, as widely as it is needed, under the pressure of the lens during the stage of its delivery.

The advantages of the method of opening the capsule are that by it we get rid of one instrument, the cystotome—an instrument hard to keep clean at the shoulder from which the pricking point projects, hard to get and keep perfectly sharp, liable from its shape to catch and damage the cornea or iris in case of sudden movement while it is in the eye, and which I have seen more than once, by its direct backward pressure, dislocate the lens and allow the escape of vitreous. Then the small opening in the capsule nearly in the direction of the corneal section seems to have a decided influence in making sure of the proper rotation and presentation of the lens in the corneal wound; and cortical matter as well as nucleus has a perfectly direct avenue of escape; and if cortical matter remains after the nucleus has been extracted, it remains inside the capsule, and not in the anterior chamber where it would exert its well-known deleterious influence on the iris; or, as some

have supposed, furnish an especially favorable culture medium for the pathogenic bacteria introduced on the shank of the cystotome or along a path of capsule incarcerated in the corneal wound. Again, with this method of opening it, there is no chance that portions of the capsule will prolapse or become incarcerated in the wound, and so complicate the healing and endanger the ultimate result more insidiously, but quite as seriously, as prolapse or incarceration of the iris.

This method of opening the capsule has this disadvantage, that when the pupil contracts, as it does in the process of washing out the anterior chamber, the iris sometimes entirely covers up the rent in the capsule and makes it much more difficult to dislodge any remaining cortical matter. Under these circumstances, it is best to make no effort to dislodge it, for, in my experience. cortical matter *left within the capsule* after the removal of the lens nucleus is innocuous, and is certain to be removed by absorption in a few weeks at the farthest, causing some delay in the full restoration of vision and detracting from the brilliancy of the operation, but in the end giving the patient the best result.

The delivery of the lens is effected by making pressure with a lens spoon backward on the lower portion of the cornea, and with a corneal spatula slightly downward upon the upper ciliary region, causing the lens to push into the pupil and engage in the corneal wound, the movement of the lens being steadily followed by a slight upward movement of the spoon, and the necessary pressure never relaxed until the greatest thickness of the lens has passed through the corneal section. It is of the utmost importance that the pressure be maintained steadily ; any intermitting of it that causes the lens to alternately advance and retreat is liable to bring about the displacement of the lens, and the presentation of the vitreous in its stead. After the nucleus has escaped, the pressure is gently continued until any evident masses of cortex have also been extruded, and then withdrawn.

Washing out of the anterior chamber I have practised after the method and with the apparatus of Dr. Lippincott, of Pittsburg, for the last year, as the principal step in the operative toilet. If the iris has prolapsed, the stream of boric acid solution is the simplest and best repositor, its effect being to carry the iris into position, and at the same time to provoke a marked and very satisfactory contraction of the pupil. If the opening in the capsule remains freely accessible, the current may be directed into it and all lenticular *débris* removed. But if this is not readily accomplished, I content myself with a thorough washing out of the anterior chamber, at the end of which the pupil is found small and central, stroking of the iris with the spatula, or poking into the angles of the cornea wound to dislodge incarcerated iris or capsule, being thus dispensed with.

Eserine is instilled after the washing of the conjunctival sac, although the effect of the irrigation of the anterior chamber has been to already secure a small central pupil, in order that this contraction of the pupil may be maintained and the iris drawn as far as possible away from the cornea. In a single case in which I omitted the use of eserine a slight prolapse of the iris appeared at the end of thirty-six hours. Eserine was then used, and the prolapse promptly reduced. Later, however, it again appeared, and the pupil was left somewhat distorted.

Simplicity. As compared with the Graefe method and its modifications, "simple extraction" deserves its name, in that the iridectomy that it dispenses with is the most painful and one of the most delicate portions of the former operation, and that the uninjured iris is more readily reduced and kept wholly within the eye than the iris that has lost the tensile action of its sphincter. It prevents the extremely insidious accident of incarceration of the capsule. Again, the dangers of that serious complication, prolapse of the vitreous, are reduced to a minimum. Without rough handling, or especially unfortunate movement of the eyeball, it is scarcely possible for this accident to occur before the nucleus is delivered. Even in a case of dislocated lens with fluid vitreous the delivery of the lens was readily effected without the use of a spoon or loop, and no vitreous was seen until this had been accomplished.

Ease. The statement is usually made that with simple extraction the delivery of the lens is slightly more difficult. But, in my experience, this is true only to a slight extent as to the complete removal of the cortical matter. The delivery of the nucleus is not to any notable extent more difficult. I operated yesterday on a case where the lens were par-

ticularly large and the cornea small. From the other eye, in which the conditions were precisely similar, I had removed the lens several months ago, after a preliminary iridectomy, with a good deal of difficulty. The simple extraction was, if anything, the easier one. After the first operation a considerable amount of cortex remained in the capsule, and the same thing occurred with the second. Still, the removal of all remaining cortex is, I believe, a little more difficult after the simple extraction, though certainly not more dangerous.

Prolapse of the iris. The danger of this complication is the greatest drawback on simple extraction—about all that keeps it from being an ideal operation. When any considerable prolapse occurs it causes a distorted pupil, is liable to delay the healing, is followed by unusually high astigmatism, and, if very large, might endanger the eye. The impression is abroad that it is very much more likely to happen after simple extraction than after extraction with iridectomy, at least, it is scarcely counted as one of the risks of the latter operation. But iridectomy does not prevent the occurrence, except of the part of iris that has been removed. Indeed, in so far as it removes the restraining influence of the iris sphincter and leaves angles of iris floating within the eye, iridectomy directly favors incarceration, the form that prolapse assumes after it. Knapp has recently reported statistics of about five hundred cases of simple extraction, with prolapse of the iris in eight per cent. of the cases. It is probable that incarceration of a part of the iris at the angles of the wound is about that common among Graefe's extractions. In my own work prolapse has not been more common after simple extraction than was incarceration after iridectomy. More than this, the great mass of cases of prolapse under the use of eserine flatten down and cause as little trouble as the incarcerations after iridectomy, and do this without excision or any other special treatment, without notably delaying the healing, and, so far as can be judged, without any additional ultimate danger to the eye. I speak thus particularly about prolapse of the iris, for it was fear of it that kept me for a considerable time from giving up iridectomy. Still prolapse of the iris is the chief danger of the method and it should be carefully guarded against by the use of eserine, by keeping the patient as quiet as possible, by avoiding any pressure of the dressing or through the dressing on the globe, and by placing the corneal section as far away from the iris as possible, compatible with making it large enough to permit the escape of the lens.

Visual acuteness. The principal advantage of the simple operation is the exclusion from the eye of a large amount of very imperfectly focussed light, and the retention of the power of adapting the eye promptly and fully to the varying intensity of the light to which it is exposed. This advantage, although shown partly by statistics of visual acuteness, can never be fully exhibited in that way. An eye may be able to decipher even the smaller test-types, although their image on the retina is engulfed in a flood of unfocussed light coming in through distorted portions of the cornea opposite the coloboma left by an iridectomy. But even with only the ability to make out the same type, the vision secured by the exclusion of this useless and confusing excess of light is for all practical purposes far superior.

Again we find in age the retina habitually guarded against even the light admitted to the younger normal eye by a diminished pupil; and the reversal of this, the flooding of the senile eye, with its slower nutritive processes, with an amount of light largely in excess of what it has been accustomed to, especially the crippling of its power to defend itself against sudden increase of illumination cannot but diminish its power of resistance to unfavorable influences, and lead to ultimate deterioration of vision.

It was watching the gradual deterioration that occurred in certain eyes that had been subjected to extraction, with iridectomy, that first made me desirous of trying the simple method.

Indications for iridectomy. I am not aware of any operator who proposes the abandonment of iridectomy in all cases. It is pretty certain that in at least one class of cases all will continue to practice it, namely, those in which from iritic adhesions or from other causes the pupil is extremely rigid and undilatable. The other indications for it are not so well agreed upon, but probably one of the most important of them is extreme restlessness and insubordination on the part of the patient. All of my cases of prolapse

have been in patients markedly of that character. For the present most of us will be apt to fall back on iridectomy for a number of reasons, as I did in a case about a week ago where there was reason to suspect a large lens and saccharine diabetes, so that I feared sloughing from a large corneal flap. But with myself, as with many others, the present tendency is to do iridectomy less and less frequently, and it is probable that the cases in which it is either necessary or desirable will ultimately be found to be few and far between.

KIDNEY DISEASE WITH CARDIAC COMPLICATIONS, WITH EXHIBITION OF SPECIMENS.*

JOSEPH M. PATTON, M.D.,
CHICAGO, ILL.

The patient, male, was 40 years old. He had been living in a Western city for eight or ten years, and his family during this period had had no track or knew anything about him until he came to this city in the care of an escort, coming from Ogden. He told me he has suffered at various times during the past three or four years from what is termed in the Western country "mountain fever," and that he had had a great deal of trouble with his liver. He had worked at printing, being a foreman in some large printing establishment, leaving that and going out into the open air and doing all kinds of hard work in the endeavor to stimulate himself to a better physical condition, and finally, after being told by his physicians that he had Bright's disease, and would live but a short time, he accepted their advice and returned to Chicago. The man who came with him did not expect him to live until he reached Chicago. I saw him twelve hours after his arrival and found him sitting in a chair suffering from violent dyspnœa, unable either to lie down, to stand or walk. The lower portion of the lungs œdematous; the lower extremities were swollen until the skin over the tibialis anticus in the left limb had bursted and was running freely with water. The liver was greatly enlarged from passive congestion until it filled three quarters of the abdominal cavity; his stomach was somewhat congested, and he was suffering a good deal of distress in this organ. He had no temperature; his pulse was rapid and irregular; the heart was in a very arhythmic condition, but was beating with a good deal of force, which was not at all commensurate with the condition of the circulation in the arterial tract. Examination of the heart revealed a very much enlarged condition of the organ, which was due partly to hypertrophy, and more so to dilatation of the left ventricle, the line of dulness extending two inches to the left of the nipple and down to the seventh intercostal space. No murmurs to be heard at the aortic valve. Of course, it would be a question in a condition of this kind as to whether or not a mitral regurgitant murmur would be present. Owing to such an extensive dilatation of the left ventricular cavity, you might have a mitral regurgitant murmur which would escape detection. The patient improved in the course of a week under treatment, which was, infusion of digitalis, morphine and nitroglycerine with diuretics, the nitroglycerine with digitalis to counteract the tendency of digitalis to contract the arterial vessels, and thus relieve the distressing condition that might be caused in this way. There was little effect on the kidneys by this treatment. He was passing about four or five ounces of urine every twenty-four hours; specific gravity, about 1023, heavily loaded with albumen; few epithelia from the bladder and pelvis of the kidney, but no casts. He was given calomel according to the method of German physicians, when administering it as a diuretic in cardiac diseases, that is, giving three grains three times a day until six doses are taken, then wait. This was taken in this way, and at the end of the second day the kidneys began to act freely, and after the third or fourth day he passed four quarts of urine in twenty-four hours. Inside of four days the œdema was out of the lungs; the liver had assumed its natural proportion, swelling of extremities disappeared, and the patient was feeling comfortable. Treatment directed toward his heart, and to improve his general condition, was continued. He did not gain in strength, and had periodical relapses into his former condition, with return of the œdema of the extremities, enlargement of the liver and extension of the dilatation of the heart, with scanty secretion of urine. These attacks were preceded by distress in the stomach and symptoms of biliary

*Read before Chicago Pathological Society, October, 1892.

colic ; they were relieved only by the administration of the calomel. These attacks were preceded by marked arhythmia of the heart and accompanied also by marked Cheyne-Stokes respiration. During the early part of my attendance he was seen by Dr. J. D. Skeer in consultation, who suggested contracted kidney as the cause of the cardiac condition, and while disease of the kidneys was the only reasonable explanation, the efficient action of these organs obtained under treatment, made it rather uncertain. He suffered three or four relapses, and was under treatment nine months, and finally died from failure of the right ventricle, there being non-synchronous contraction of the ventricles prior to death, and at the time of death there was very little œdema, only such as one would naturally expect. The kidneys were acting fairly well until two days prior to death, when they gradually ceased their action as would be expected from a failing heart. The Cheyne-Stokes breathing was only present during the attacks above alluded to, and was not present for three weeks prior to death.

The autopsy was made with the assistance of Drs. J. D. Skeer and Geo. H. Cleveland sixteen hours after death, and showed that the body was fairly well nourished.

Autopsy sixteen hours after death: Body fairly well nourished, *rigor mortis* not well marked. There was no fluid in the pericardial sac, the left pleural cavity contained about a quart of clear fluid, the right pleural cavity was empty. A firm band of old adhesions about two inches wide connected the chest wall and middle of right lung. The lungs were much congested, and the seat of brown induration almost black in places, very firm and indurated in spots, as from connective tissue induration subsequent to hæmorrhagic infection, or catarrhal pneumonia ; lungs œdematous in lower portions, especially the left.

Heart weighed 22½ oz., hypertrophy of all muscular structures of heart, and dilatation of all cavities, granulo-fatty degeneration of muscular tissue. Mitral ring stretched, papillary muscles much thickened, and retracted, preventing closure or mitral valves. Mitral valves slightly thickened. Aortic and pulmonic valves were healthy. Tricuspid opening slightly stretched. A long firm white thrombus in right venticle stretched back into right auricle, and required some force to detach it from papillary muscles ; a small softer clot in left ventricle ; both ventricles and right auricle were filled with clotted blood.

Liver enlarged, firm and seat of fatty degeneration and moderate cardiac cirrhosis. Gall bladder distended with dark green bile, ducts patent. Stomach congested, slightly dilated. Pancreas enlarged, congested and very hard.

Right kidney weighed 8½ oz., of normal consistency and appearance, capsule non-adherent ; ureter larger than normal. Left kidney weighed 1½ oz., capsule very much increased in thickness, impossible to separate it without tearing kidney tissue. Kidney itself very hard, contained in cortical portion several small cysts filled with an amber colored fluid, ureter very small.

Dr. Skeer questioned the patient one morning as to his ever having had syphilis, and he said yes ; but in talking to him afterwards it was evident that he misunderstood the doctor ; that he understood him to mean any kind of venereal disease. He had had gonorrhœa and admitted it, but he denied ever having syphilis.

An examination of the specimen shows that the aortic valves are intact. It was opened between the junction of the two cusps of the valve, so that they are not destroyed. The mitral ring is considerably stretched and the valves are retracted, and it was rather difficult to state whether they have been the seat of more or less inflammation. Of course, they are thickened and retracted, but that might be due to the thickening and retraction of the ring and papillary muscles. The wall is much thickened, and the cavities are all dilated. The right kidney is of no particular interest except that it is enlarged. In the left kidney there were several cysts. They were not opened, and they have dried up a good deal.

These cysts are here found in their usual situation, that is in the cortical portion, especially near its surface. This kidney is a marked example of the small red kidney—chronic interstitial nephritis, the marked thickening of the capsule, and the direct connection of the capsular connective tissue with that of the cortical portion is very marked. The decrease in the cortical substance, especially that between the pyramids, is more marked than is usually found ; the pyramids themselves have diminished considerably in

size as the result of connective tissue increase in the medullary portion, a somewhat infrequent occurrence. It is possible that there was entire functional inability of this organ for a long time, which might explain the absence of the usual evidences of disease found in the urine.

A point of interest in this case was the diagnosis. It was evident the man had an hypertrophied and dilated heart, but it was not evident as to what that was due. There evidently had been hypertrophy of the right ventricle which had taken considerable time in developing, and of course there must have been a cause for that. The aortic valves were intact; there was no regurgitation or stenosis; there was no apparent sclerosis of the arteries; there was nothing that one could find which would explain the enlargement of the heart, unless it might be contracted kidney. After administering remedies to him and finding the secretion of urine was so free, and that it went on with the improvement of the circulation for months without any special trouble, there was no room to suspect that there was anything wrong with his kidneys. There was no evidence of any kidney disease by examining the urine, except occasionally traces of albumen, which will show in any case of congestion of the kidneys from deficient circulation.

Another point: It is evident that the enlargement of the heart would come under that head designated by Fraentzel as idiopathic enlargement of the heart. It is due to some cause extraneous to the heart, obstruction to the circulation in the kidney, or some other agent; excessive consumption of food and drink, for instance, might cause idiopathic enlargement of the heart by increasing vascular tension. This case might be classed as one of idiopathic enlargement. How long this condition of the kidney might have been developing it is hard to say; but no doubt it was excited years prior to the man's death, or it may have developed in early life. How long a man would live with one kidney; how long it would take to produce that amount of enlargement of the heart which we see in this case and its consequent failure are very interesting questions. It is possible the trouble with the kidney might have begun in early life. It is also possible that it might have been a matter of only five or six years back. Certainly, it would take five or six years for a heart to develop the condition of hypertrophy developed in this case, with the consequent degeneration and dilatation. In aortic stenosis, which gives us the form of hypertrophy more nearly allied to this than anything we can think of, we might have a heart running for a period of thirty or forty years before it reached the condition of degeneration and dilatation which obtained in this man. The compensation effected by the right kidney is an interesting fact, as it must have done double duty for a long time, and while under my observation I think the entire function devolved on this one organ. In no other way can I explain the lack of evidence of kidney disease usually obtained by examination of the urine. I do not think the left kidney excreted any urine during the nine months in which the case was under my observation.

This case is also instructive in showing how much may be done in prolonging life in these cases under very adverse conditions.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 9, 1891.

THE PRESIDENT, JOHN B. ROBERTS, M. D., IN THE CHAIR.

DR. A. B. KIRKPATRICK read a paper on "The Medical Treatment of Appendicitis" (see page 84).

DISCUSSION.

DR. CHARLES P. NOBLE: I arrived a little late, but I understand that reference has been made to a case which I saw in consultation. It was undoubtedly a case of intussusception. The case illustrates the fact that occasionally a patient will recover from this condition by sloughing of the bowel. It also illustrates the difficulties of diagnosis of the cause of peritonitis when the surgeon is called in late. The boy had been sick for nearly a week when I saw him. There was evident obstruction of the bowels, with fæcal vomiting, and there was undoubtedly well-marked peritonitis; and the history indicated that the peritonitis had arisen in the right iliac region. The question was whether the case was one of appendicitis or one of intussusception. The physicians in charge were inclined

to regard it as a case of appendicitis, and and I agreed with them, as the symptoms of invagination were absent; yet I must say that I felt that intussusception through the anus, but it was so high that my finger barely touched it, and I was not sure that it was not a fold in the bowel.

It is fortunate for that boy that our advice was not followed; for if he had gone to the hospital and been operated on in the condition that he was in, the chances would have been much in favor of a fatal result. At the same time, I think that it would be exceedingly dangerous to argue from such an exceptional case any general rule of practice. The recoveries in this class of cases, where the bowel is allowed to slough away, I think, does not exceed two or three per cent.

Dr. T. S. K. Morton: The first case reported is of interest from the fact that it was a well-marked case of intussusception, and yet the classical symptoms of this condition were absent. There was no passage of blood with the stools, and there was absence of rectal irritation. The condition was about as marked as it possibly could be, and yet a diagnosis apparently was not possible.

I think that the position of the surgeon in regard to appendicitis is often misunderstood, especially by the mere medical practitioner. So far as I have seen, the surgeon is not anxious to operate, and the cases not operated on vastly exceed those in which operation is done.

With reference to the constipation of appendicitis, I think that where the bowel cannot be moved by any procedure either from above or below, the case is exceedingly unfavorable for recovery, with or without operation; whereas, if the bowels can be moved, the prognosis becomes much more favorable. If, after the bowels are freely moved, the symptoms subside, I look upon the case as one that will probably not require operation at that time. If, however, there is only temporary amelioration of the symptoms, or none at all, the case is one for operation.

Dr. William S. Stewart: I am not satisfied that the cases reported should be regarded as true cases of appendicitis. There was evidently impaction of the ascending colon in all five cases, due, no doubt, to inflammatory action; but it is evident that in these cases operation was not justifiable. First remove the impaction, and then if there is an aggravation of the symptoms, the imflammation becoming more marked, it is then time to consider the propriety of surgical treatment.

Dr. Kirkpatrick: I am sorry that no one has attempted to throw light upon the subsequent course of the first case reported, as to whether the typhoid condition which followed was due to the inflammatory trouble or was a true typhoid fever.

I should not like to be considered, in this paper as not favoring operation in proper cases. The point which I wish to make is, that I fear in some cases the physician does not take the proper means to open the bowels before resorting to operation. I fully agree with what has been said as to the unfavorable prognosis of operation in cases where the bowels cannot be moved at all.

I think the criticism of (I believe) Dr. William S. Stewart hardly just or tenable. I understood him to say that he did not believe the cases reported were true cases of appendicitis—only obstruction of the bowel. I took particular care not to report in detail the cases in which I relied upon myself for diagnosis, but based my treatment upon the diagnoses of Drs. Keen, Noble, Wheeler, Dripps, and David Stewart.

I think we must admit that they are careful, skilful men, and capable of making a correct diagnosis.

THE STREAM OF IMMIGRATION.

Reports to the State Board of Health, from the Sanitary Inspector in charge of the inspection of immigration to exclude dangerous diseases, at Port Huron, for the two weeks ending December 19, 1891, show opportunities for the introduction of such diseases, by immigrants from many different countries, passing through Michigan to States beyond. The numbers and nationalities of the immigrants inspected were as follows:—6 Arabs (from Jerusalem), 14 Austrians, 8 Belgians, 27 Bohemians, 49 Danes, 84 English and Scotch, 1 Finlander, 34 French, 97 French Canadians, 204 Germans, 20 Hollanders, 10 Hungarians, 6 Irish, 101 Italians, 209 Norwegians and Swedes, 66 Poles, 12 Russians, 36 Russian Jews, 2 Servians and 5 Swiss.

The destinations of these immigrants were mainly "Chicago and the Northwest." A few of them went to Saginaw. All the French Canadians were from the province of Quebec.

SELECTED FORMULÆ.

CHOLELITHIASIS.

Dr. Huchard (*Centralblatt für d. ges. Therapie*, No. 8, 1891) recommends :

℞
Natrii benzoici, } āā gm. v.
Natrii salicyl, }
Pulv. rad. rhei, }
Pulv. nuc. vomic., gm v.

Sufficient for twenty capsules. One capsule at eve y meal.

ODORLESS IODOFORM SALVE.

The following (*Centralblatt für d. ges. Therapie*, No. 8, 1891) is suggested :

℞
Creolin.....grammes j.
Iodoformi..... " ij.
Vaselin..... " xxv.

BEJEAN'S GOUT CURE.

According to the *Pharmaceutische Centralhalle*, this remedy has the following composition :

℞
Oil of wintergreen .....parts v.
Extract of gentian..... " v.
Iodide of pot ssium..... " iv.
Sodium salicylat ..... " iv.
Alcohol..... " xx.
Water..... " lxxx.
M.

LAXATIVE.

℞
Ext Colocynth Co.....ʒ j.
Ext. Hyoscyam.
Aloes Pulv. Soc.....āā grains x.
Ext. Nucis Vomicæ ..... " iij.
Podophylli
Ipecac.....āā " j.
Make twelve pills. Sig. One at bed-time.

—*Weekly Med. Rev.*

FISSURES OF THE TONGUE.

The following (*Lo Sperimentale*, No. 14, 1891) is recommended :

℞
Acid carbolic.....grammes 2.5.
Tinct. iodii } .....āā " 12.5.
Glycerine }

INFANTILE INSOMNIA.

M. Huchard gives the following :

℞
Urethane..... gramme 0.20
Aquæ tiliæ destillatæ.
Aquæ aurantii flavæ.
Syrupi simplicis.....āā grammes 20 00.

M. Sig. A dessertspoonful every two hours in a wineglassful of water.

—*Journal des Sciences Médicales de Lille*, August 14, 1891, p. 166.

FOR PELADA.

Water of ammonia.....1.
Rum.....3.
Decoction of walnut leaves.....40 to 60.
Use as a lotion.

TO PREVENT THE PITTING OF SMALL-POX VESICLES.

Dr. Bertrand (*Gaceta Sanitaria de Barcelona*, July, 1891) recommends :

℞
Acid boric.....grammes 4.
Amid. glycerolat..... " 50.
Apply immediately after the eruption appears.

TOPICAL APPLICATION IN DIPHTHERIA.

Dr. Ernest Timmermann writes in *The Medical News* that he has used with signal success the following formula as a topical application to the throat in the treatment of malignant diphtheria :

℞
Acid sulphurosi.....f ʒss.
Liquor potassæ.....gtt xl.
Aquæ calcis.....ad f ʒiv.

Mix, filter ; keep well corked in a cool place. To be applied topically to the throat by means of a sponge, probably every hour or two.

CONSTIPATION IN INFANTS.

Calcined magnesia,
Powd. rhubarb,
Oleosaccharum of anise, aa 5 parts.

Administer a pinch of the above three times a day in the constipation of children of 1 to 2 years old; if the infant is only s me weeks old, make both the rhubarb and magnesia 3 instead of 5 parts. [The oleosaccharum is made by intimately mixing one or two drams of the essential oil of anise with one ounce of finely powdered sugar.]

GONORRHŒA.

Dr. Netzetzky (*La Independencia Medica*, No. 42, 1891) uses the following injection in gonorrhœa :

℞
Balsam copaibæ ..... grammes 4.
Vitell. ovi, ... No. 1.
Aq. destillat ..... grammes 180.
f. emuls. et adde :
Ext. belladon. } .....āā dgms. 5.
Zinci sulfat. }
Aq. laurocerat .... dgms. 4.
Inject into the urethra four times a day.

Of service in all forms of gonorrhœa.

FOR RHEUMATISM AND LUMBAGO.

Hollister gives the following in doses of 1 teaspoonful three or four times a day :

℞
Potassium iodide,.....grammes 15.
Potassium bromide..... " 15.
Tincture of colchicum seed... " 30.
Syrup of bitter orange-peel... " 50.
Distilled water..... " 150.
M. S g The dose should be augmented until the bowels are moved.

—*National Druggist*, September 15, 1891.

ASTRINGENT GARGLES.

The *American Journal of Pharmacy* gives the following formula for Goddard's astringent gargle :

Fol. rosæ rub.....2 dr.
Aquæ bullientis.....5 oz.
Acidi sulphurici dil.....½ dr.
Infuse, when cold strain, and add
Mel. despumati.....1 oz.
Acidi tannici.....2 scr.
Aluminis.....2 dr.
Spir. vini rectifi ati } .....āā 6 oz.
Aquæ rosæ }
M.

Another gargle is as follows :

Red rose petals.....2 dr.
Pom egranate rind.....4 dr.
Boiling water.....6 oz.
Infuse, strain, and add
Alum.....2 dr.
Clarified honey .....1 oz.
Mix, filter.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by postal note, money order or registered letter.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

"The Medical and Surgical Reporter" stamped in gilt on the back.

PRICE, 50 CENTS.

PLEASE SEND MONEY WITH ORDER.
Address,

THE BUTLER PUBLISHING CO.,
P. O. BOX 843. PHILADELPHIA, PA.

LEADING ARTICLE.

NEURASTHENIA, AND ITS RELATIONS TO MENTAL DISEASES.

No subject within the entire range of medical science should demand more careful study at the present day than the protean-symptom-group we call neurasthenia. Apart from the fact that in the eastern and northern parts of this country it is probably the most prevalent of all diseases, it should also be remembered that it has been called the "American disease," by Beard, who, in 1868, described the conditions of nervous exhaustion under this collective name, and who also wrote that its development was directly due to "modern civilization."

We all have realized how frightfully common it is, and know that its expression is more varied than even the manifestations of "*malaria*," and surely no other disease exists which is of more practical importance to the general practitioner, for it rests almost solely with him whether neurasthenia shall "increase in the land." It is the general practitioner, the family doctor, who has the rarest opportunities for studying the beginning of these symptoms of lowered nervous tone, and who, therefore, must be most practically interested in their prophylactic and curative treatment, as well as in understanding, as far as our knowledge makes this possible, their real nature or *pathology*.

Is it too much to say that the treatment of neurasthenia requires more experience, judgment and fine tact than does that of any other known disease? If this is so, and in our opinion it is at least very nearly so, certain accurate knowledge is essential to their proper understanding of any given case, for only upon correct ideas as to the real state of the nervous system exhibiting these varied symptoms can a useful therapeusis be based. It is, therefore, most desirable that every physician should, as far as possible, appreciate fully the meaning of every symptom

which may herald neurasthenia, so that in a very large proportion of cases its dangers can be averted. We fear that sometimes, we hope not often, deplorable results follow, because the physician in charge of the case disregarded, overlooked or neglected to give proper weight to early neurasthenic symptoms.

So far, we have considered simple neurasthenia, or the symptoms of nervous exhaustion, but greater interest still attaches to this subject when we come to consider the relations which nerve exhaustion bears to definite diseases of the mind. Are melancholia and mania, and other common varieties of insanity frequent sequences of neurasthenia? What proportion of neurasthenics become insane? What proportion of the insane first suffered from neurasthenia? Does insanity become more prevalent in proportion to the prevalence of neurasthenia? These and many other questions naturally occur to us.

Having endeavored to indicate a few of the reasons why neurasthenia should be of special interest to the general practitioner, it is our purpose to briefly sketch the subject as its literature reveals it to-day. Space will not permit of more than a brief synopsis of some of the latest and most important thoughts.

Among the most valuable recent contributions to this subject, perhaps that of Dr. Edward Cowles (The Shattuck Lecture. Medical Communications of the *Massachusetts Medical Society*, 1891) can be justly called the most thorough and complete, especially in more clearly than hitherto defining the relations which neurasthenia has with unmistakable mental diseases. The author of this valuable paper has had, from his wide experience as chief of the McLean Asylum at Somerville, Mass., the most ample opportunities for the careful study of this affection, and his large experience and scholarly attainments add weight to his words. He regards neurasthenia as a real pathological condition of the nerve centres due *primarily* to overstrain, fatigue, etc.; *secondarily* to the exhaustion of other diseases; and *hereditarily* to various exciting causes acting upon unstable cell nutrition. The underlying cause of the lowered nutritive activity of the cell protoplasm he mainly regards as an auto-intoxication from waste toxic products, the result of over-functional work, or of disorders of the eliminating functions of the body, or of unstable metabolic action from bad heredity. In support of these views of the etiology and pathology of nerve exhaustion, the author goes exhaustively into the chemistry and physiology of the nervous mechanism, and also adduces all the recent proof which goes to show that auto-intoxication of the organism is more than probable in the conditions under consideration. This part of his work he sums up as follows: "The study of the general organic mechanism, so far, shows that it may be conceived as made up of many minor mechanisms which may be studied as represented by their activities. Some general truths have been reached in regard to all of them as to their structure, their co-ordinations, and the results of their functional exercise. These conclusions are in support of my first proposition, to the effect that when the mechanism is put into use, physiological activity and toxicity always occur together, and that the condition thus jointly produced has its first expression in normal fatigue. Moreover, it appears that in pathological or nervous exhaustion, which constitutes neurasthenia, there results a condition of "excessive irritability and weakness" of the nervous system. There is also, in acute neurasthenia, always an increased toxicity, by its accumulation in fatigued areas, and often by general fatigue and auto-intoxication through disordered nutritional processes."

Having thus concluded regarding the pathology of nerve exhaustion, he next demonstrates that there are mental symptoms by which we may know the degree

of nervous fatigue and "auto-intoxication of the nerve and muscle elements," as a "guide for diagnosis, prophylaxis and treatment." Dr. Cowles says: "My observations in the treatment of insanity have given me the conviction that in the commonly occurring and typical forms of mental disorder, which are of a functional and curable character, nervous exhaustion always plays an important part, both in the attending conditions and the causation." He strongly insists that the mental symptoms of neurasthenia being the earliest, are far more important, and better guides to treatment than the purely physical ones, and his treatment is based upon the recognition of the state of the nervous system from a careful study of the mentality of the patient. His treatment of the objective symptoms includes elimination, nutrition, rest, exercise, massage and the promotion of sleep.

Dr. Dana, of New York, has recently given us a good definition of neurasthenia. (Neurasthenia. *The Post Graduate*, January, 1891.) He says: "Neurasthenia is a morbid condition of the nervous system, whose underlying characteristics are excessive irritability and weakness; a condition in which the nutrition of the nerve cell is primarily at fault."

It is now a well recognized fact that neurasthenia may confine itself to a limited area of the nervous system, hence we have the subdivisions of cerebrasthenia and spinal neurasthenia, with their legions of symptoms, chiefly subjective. Among the objective signs of the neurasthenic condition, Dr. B. Sachs lays stress upon the following: tremor of the face, tongue and hands, and exaggeration of the knee-jerk. (Clinical Lectures. *International Clinics*, April, 1891.)

There can be no doubt from the mass of available evidence that neurasthenia and actual insanity possess, in general terms, the same etiology, and that the former may, and very commonly does, merge gradually into the latter. It is a nice question, sometimes, to decide between ordinary acute melancholia and the mental depression which accompanies certain forms of neurasthenia, and probably the formation of delusions of persecution, or that the patient is being punished for imaginary crimes, constitutes the most really practical guide towards a decision in such cases.

The treatment of these neurasthenic states is certainly most important in view of their natural tendency towards grave mental disease. It will often prove the prophylactic treatment of insanity. The success of any treatment depends mainly upon the recognition of the state of the nerves' mechanism, as shown, first, by the mental symptoms, and secondly, by the subjective sensations and objective signs which the patient presents. Routine treatment of these cases (with strychnine, phosphorus and the various tonics, the rest cure, massage and electricity, foreign travel, etc.) is to be deprecated, for only will the needs of each patient be ascertained after a careful study of the type and degree of the nervous exhaustion based upon a thorough understanding of the real state of the nerve elements, as shown by the mental symptoms, together with the condition of bodily nutrition; and, in all cases, it is our duty to endeavor to find out exactly what is interfering with nutrition. No subject within the scope of medicine is at times more perplexing than the treatment of neurasthenia, nor does any other disease offer greater inducements for the proper solution of the problem of treatment than nervous exhaustion.

The practical lesson which the recent researches concerning the essential pathology of nerve exhaustion should teach, seems to be that we should give increased attention to the *mentality* of neurasthenics, since it is the earliest and most valuable guide, according to high authorities, to a correct appreciation of the nature and degree of the nervous malady; and, also, that the treatment of such states must be varied to suit individual

cases, and the existing conditions of digestion, assimilation, cellular metabolism, elimination and excretion of toxic waste products.

The intimate relation of nervous exhaustion to insanity, on the one hand, and to neurasthenic symptoms on the other, plainly indicates that in all probability they are simply links in one pathological chain of events, and that many cases of insanity spring directly from neurasthenic soil, whether hereditary or acquired. Through the recent brilliant results obtained by the experimental chemist and physiologist, some of the shadows which obscure the pathology of neurasthenia have been cleared away, and enough is positively known to indicate that there is for nervous exhaustion always a definite pathological anatomy, and that this consists of certain changes in the nerve cells, due to the effects of the toxic products resulting from their pathological activity.

CORRESPONDENCE.

PROMISCUOUS SPAYING OF WOMEN.

DR. NOBLE'S REPLY TO DR. TODD.

EDITOR MEDICAL AND SURGICAL REPORTER:—It is much to be regretted that Dr. Todd in his communication in the last issue of the REPORTER has followed the lines of his previous letter. He reiterates his statements, but fails to furnish any evidence in support of them. He is silent even with reference to the real nature of the four cases of removal of the uterine appendages which have come under his own notice. The only new point presented is that a woman, the mother of four children (whether with healthy or diseased ovaries the Doctor does not state, although presumably they are healthy), has consulted him with reference to having her ovaries removed in order to avoid further pregnancies, and that in spite of his advice to the contrary, she persists in her intention, and expects to get some surgeon to do her bidding, because she can pay for it. Also, that the woman knows several other women who have "gone through the operation." Nothing is said as to the nature of the indication in these cases, whether tumor, abscess, or chronic salpingitis. It is not stated that any one removed this woman's healthy (?) ovaries, or agreed to remove them, but simply that the woman intended to have it done. Yet the Doctor says that this fact proves conclusively to him that there are certain parties who follow the profession of the promiscuous spaying of women! It is scarcely necessary to point out that the evidence required to convince him is not great.

Dr. Todd says that his criticism applies to "a certain class of ambitious young surgeons." Here again he gives no reason for stating that ambitious young surgeons do other than justifiable operations; hence the statement does not require special comment.

As was stated in my last communication, my object in writing it was not to criticise Dr. Todd, but to protest against the baseless assumption of not a few members of the profession that healthy ovaries are being removed by operating gynæcologists, and further, to protest against the present fashion of making loose statements concerning this subject. This whole matter is a very serious one for the profession and for sick women; and every candid and fair man must desire that it shall be approached, not from the standpoint of mere opinion, which may be only prejudice, but from the judicial or scientific point of view, in which truth is the only object, so that a conclusion can be reached upon evidence which is satisfactory to every mind.

It seems curious that this subject now should agitate the minds of many members of the profession in general, when it has been settled practically by gynæcologists themselves. Some years ago, following the lead, but not the moderate practice, of Battey, surgeons removed many healthy or slightly diseased ovaries for various mental and nervous diseases, supposed to be connected with menstruation. The results obtained, as might have been expected, were such as to cause the older gynæcologists to operate on such cases only after the failure of all simpler measures, and then only under strict limitations. This experience of the older men has been of immense advantage to younger men in enabling them to escape this error in practice. Besides, our knowledge, or rather ap-

preciation, of the pathology of pelvic inflammation has undergone a complete revolution within the past ten years, which has been of the greatest value in giving gynæcologists to-day a rational basis for their therapeutics.

Had the letter of Dr. Todd, and similar communications, been written ten, or even five, years ago, they would have assisted in bringing about the principles of practice which the good sense of gynæcologists has caused them to adopt.

The fact that a woman consulted Dr. Todd with the object of having the ovaries removed to escape future pregnancies is worthy of careful consideration. It seems to me that an operation done for such a purpose would be malpractice. The only ground on which it could be justified would be in case of serious pelvic deformity, making delivery *per vias naturales* dangerous or impossible. But the modern Cæsarean section, done at or just before the beginning of labor by an expert surgeon, is so safe that even here the indication is very questionable.

Very respectfully yours,
CHARLES P. NOBLE, M. D.

NON-MENSTRUATING PLURIPARA.

EDITOR OF THE MEDICAL AND SURGICAL REPORTER:—On page 834 of REPORTER, of volume lxv, Dr. Marion Dunagan quotes a case of a colored woman who had never menstruated, who was the mother of ten children. Will you allow me to report the following: In 1878, I attended a Mrs. D—— in her sixth confinement. She stated to me, and her husband confirmed the statement, that she had never menstruated and never wore a guard. She sent for me a month before delivery, believing herself at full term, stating that she "did not know for a certainty when she was at full term," owing to the fact that the usual data were not present to date from. Afterward she gave me in a vial two ova, unruptured, which she had found on her night dress.

I believe Dr. Dunagan is right as to menstruation and ovulation not occurring at the same time, and that neither are dependent on the other. I have a record of eleven cases where connection was not had with the woman until fourteen or fifteen days after menstruation and for a month prior to it, and still conception took place. In two other cases women have shown me the perfect ova which have been thrown off sixteen or twenty days after menstruation—they not knowing what "the little pellets" were.

I have no doubt but that numbers of physicians have met such cases but thought them of not sufficient importance to report.

Incidentally, I may state that I know also of a case where a lady of eighty-three who menstruated regularly every two months, the same as when she was a young woman. She had never menstruated every month as is usual.

BEN. H. BRODNAX, M. D.
Brodnax, La.

DR. E. W. CAMPBELL'S ARTICLE ON "ELEMENTS OF THOROUGH DIAGNOSIS."

EDITOR OF THE MEDICAL AND SURGICAL REPORTER:—Dr. E. W. Campbell in his article in the Dec. 26th issue of the REPORTER, entitled, "Elements of Thorough Diagnosis," affords a remarkable example of the fact that certain impressions transmitted by the optic nerve, under certain conditions, can so influence the brain as to make it reproduce the same impressions on some other occasion with the belief that they are original. The case above cited is remarkable in that the ideas of the article and the language by which they are expressed are identical with part of the introduction to Da Costa's "Medical Diagnosis."

I feel obliged to the author of the article for placing in my hands so convenient a copy of the instructions of the great Da Costa.

Respectfully,
J. F. STEWART, M. D.,
Griffen, Ga.

CONSTIPATION.

In a lecture on Constipation, the eminent authority on therapeutics, Prof. Dujardin Beaumetz, described Villacabras as the most highly concentrated purgative water known. Its usefulness seems to be by no means limited to the field which is occupied by other waters. Its action is not succeeded by the annoying constipation that usually follows the administration of other purgative waters. An ordinary wine glass of Villacabras, taken before breakfast, produces a soothing effect upon the bowels and results in a natural movement within two or three hours.

BOOK REVIEWS.

THE COMPARATIVE ANATOMY OF THE DOMESTICATED ANIMALS. By A. CHAVEAU, M. D., LL. D. Second English Edition. Translated and Edited by GEORGE FLEMING, C. B., LL. D., F. R. C. V. S. 8vo, pp. 1084, 585 illus. New York: D. Appleton & Co. 1891.

This edition is a translation of the fourth French edition, issued last year. In the present volume, numerous alterations, additions and illustrations have been made in order to render it fully up to the requirements of a text-book and standard work of reference. The chief additions are on the anatomy of the ass, mule, rabbit and camel, and one hundred and thirty new illustrations. The pages have been enlarged, and the letter-press substantially improved. There is also a copious index, which is not found in the French edition.

Chaveau's work has long since attained a position second to none in the field it is intended to cover. In this new edition, the student of veterinary and comparative anatomy will find a work accurately written, fully illustrated and generally admirably adapted to his wants.

EVIDENCES OF THE COMMUNICABILITY OF CONSUMPTION. By G. A. HERON, M. D. (Glas.), Fellow of the Royal College of Physicians of London; Physician to the City of London Hospital for Diseases of the Chest. 8vo, pp. 163. London and New York: Longmans, Green & Co. 1890.

During the winter of 1889, Dr. Heron delivered two lectures at the London Hospital for Diseases of the Chest, on "The Question of the Communicability of Consumption." These lectures met with such approval, and were of such value for reference, that he has been induced to put them in book form.

The death-rate from tuberculosis is so appalling that anyone offering facts which will serve to diminish it, must be looked upon as a public benefactor. Certainly the lectures before us entitle the author to such a recognition.

In the book, the wording of the original lectures has been somewhat modified, additions have been made, but the colloquial style of the lectures preserved. We find chapters on the researches of Koch concerning tuberculosis, the evidences of the connection of specific bacteria with the disease, the haunts of the bacilli, the evidences showing the communicability of consumption, milk and meat as sources of infection, prophylaxis, etc. There is also a valuable appendix by Dr. Frosch, of Berlin, prepared under the direction of Professor Robert Koch, giving references to recent contributions on the infectiousness and contagiousness of this disease.

Dr. Heron is a firm believer in the bacteriological origin and contagiousness of consumption, and his facts have been presented so clearly and convincingly that one cannot read his work without feeling that he has built upon an indestructible basis. The book is of such a character as will interest every one having the welfare of the community at heart, and who desires to prevent the spread and continuance of this terrible scourge of mankind.

PERISCOPE.

THERAPEUTICS.

THE HYPNOTIC ACTION OF THE ANTIPYRETICS.

In the *Deutsche Medizinal Zeitung* for June 5, 1891, Professor Bernheim calls attention to the great similarity in action of the so-called antipyretics,—quinine, salicylic acid, antipyrin, antifebrin, phenacetin, etc.,—not only in their antithermic, but also in their hypnotic action. When the favorable action of salicylic acid in rheumatism was first observed, it was designated as a specific for this affection, but experience has taught that the other antithermic remedies produce a favorable effect likewise in the same manner,—that is, they diminish articular pain without influencing the course of morbid processes itself. According to Bernheim, the connection between antithermic and analgesic action is the following: Fever originates through the absorption into the blood of pyrogenic substances, which act as stimulants to the heat-centres, and reduction of temperature can be produced by the elimination of these pyrogenic substances or by direct action on the heat-centre. If the antithermics were capable of actually destroying the ferments in the blood they would then act as abortive agents. This is, however, not the case, according to Bernheim, who will not even admit a specific action for quinine in the case of malaria, since he maintains that the

action of this substance on the disease is merely due to its antithermic properties, which are possessed in almost equal degree by the other antithermics. He concludes that the different antipyretics, quinine and salicylic acid included, only produce their action either through antithermic influence on the cerebral centre, and that a distinct antipyretic action within the organism has never been demonstrated. He likewise maintains that the analgesic action is in close connection with the antithermic action, and likewise is produced by influence of nerve-centres, which are probably included in the gray substance of the cortex. In fact, Bernheim states that by the æsthesiometer he has succeeded in producing marked reduction in the sensibility of the skin after the exhibition of quinine. According to this, therefore, the antipyretics are only indicated in fevers in the height of temperature, or when they are to be employed for the reduction of abnormally increased sensibility.

CORNUTIN AS A HÆMOSTATIC IN HÆMORRHAGES FROM THE BLADDER AND FEMALE GENITALS.

Dr. Wilh. A. Meissels (*Wiener med. Presse*, No. 42, 1891) recommends cornutin muriate or citrate as an efficacious hæmostatic in vesical and uterine hæmorrhages. It may be administered subcutaneously or by the mouth. It is equally efficacious in males as well as in females. The dose employed was one to one and a half centigrammes (one-eighth to one-fourth of a grain) a day. It is easily taken and supported by the stomach.

CHLORIDE OF AMMONIUM IN INFLUENZA.

According to the Paris correspondent of the *Lancet*, at a recent meeting of the Academy of Medicine, M. Marrotte advocated the use of chloride of ammonium in the treatment of epidemic influenza in preference to sulphate of quinine, as urged by M. Gellié, of Bordeaux, in his recent paper read before the academy. M. Marrotte speaks very highly of the results obtained by chloride of ammonium, the advantages of which over quinine he claims to be that it is much cheaper, more rapid in its action, and brings about a more complete and definite cure. It is more especially in those forms of the disease which are complicated by pulmonary congestion or inflammation that chloride of ammonium will be found serviceable. From 50 to 80 grains may be given in twenty-four hours in the form of 8-grain powders, which may be conveniently concealed in a wafer. As the treatment of influenza is, unfortunately, like many other therapeutic problems, a very open question, perhaps some of your readers on your own side of the channel, whose opportunities just now are only too unlimited, might put the drug to the test and record their experience.

HYDROTHERAPY IN THE TREATMENT OF DIPHTHERIA.

The whole body of the child from the neck down is enveloped in a Priessnitz pack. This is removed at the end of three hours and the whole body rubbed off with cool water. After this, the body is again enveloped in the Priessnitz pack from the neck to the hips. These packs are renewed about every fifteen minutes during the following hour or two.

This whole procedure repeated twice, so that the child lies in a constant sweat from six o'clock in the morning to twelve o'clock at night. To promote diaphoresis, elder-tea and cognac in sugar water are freely administered.

From midnight until six o'clock in the morning, the child is allowed to rest, only a small Priessnitz pack enveloping the neck. Internally, chlorate of potash (2 per cent.) is administered.

This treatment usually causes the membrane to disappear within from two to four days. The fever and the bad smell as a rule vanished on the second day. The more copious the perspiration, the more rapidly does the membrane loosen.

Out of 117 cases of diphtheria treated as above described, 14 died. Tracheotomy was required in 9. The time spent in the hospital varied from six to eight days for each case.

As a theoretical argument in favor of the sweat treatment, it may be stated that it augments pressure of the secretion in the mucous glands, thereby loosening the false membrane, which is especially held in place by the fibrin net sunk into these glands. Moreover, the stimulation of the lymphatic circulation promotes the elimination of the poisonous elements from the body.—*Blat. f. Klin. Hydroth.*

TREATMENT OF ANGINA PECTORIS BY COCAINE.

In a paper in the *Revue de Médicine*, the use of cocaine is strongly recommended in angina pectoris, in doses of one-half to one-third of a grain three or four times daily. He quotes four cases of this disease which were benefited greatly by this treatment. If the attacks do not cease immediately after taking the remedy, they completely yield to it, however, in about three days. Under its use the pulse becomes slower but fuller, and the quantity of the urine is augmented. The author refers to some observations previously made by him, which appeared to show that the inhalation of oxygen in this disease did much good; he therefore suggests that it should be tried in conjunction with the internal administration of cocaine.—*Med. Chronicle.*

A NEW TREATMENT OF GRANULAR CONJUNCTIVITIS.

The usual treatment of granular conjunctivitis consists in turning back the eyelids with the fingers, and then cauterizing the portion of the conjunctiva thus exposed with the sulphate of copper. This daily cauterization is extremely painful, and does not produce cure until after many weeks of severe suffering, and sometimes did not prevent absolute blindness.

At the meeting of the Académie de Médecine, held on August 4, 1891, Dr. Abadie described a method in the first place of completely everting the upper eyelid so as to expose the superior conjunctival cul-de-sac (*La France Médicale*, August 7, 1891). In the ordinary method of procedure it is this part of the superior cul-de-sac which is never exposed, and which is ordinarily a veritable focus of infection. To accomplish this complete inversion of the eyelids special instruments are necessary, and the patient must be chloroformed on account of the severe pain produced by this manœuvre. The eyelid is seized with forceps, and then rolled twice upon itself, or, in other words, rolled twice completely around the forceps, so as to completely expose the superior conjunctival cul-de-sac, which is then scarified freely with a bistoury, and a fairly hard tooth-brush is then dipped in a solution of corrosive sublimate, 1 to 500, and the raw surface vigorously brushed with this solution. This procedure is only required once, and then on subsequent days the eyelids are simply everted in the ordinary manner and the conjunctiva bathed with a solution of sublimate. The author states that this method of treatment may be applied to all cases, no matter what may be the existing degree of complication, and that its efficiency is the more marked the more serious is the case.

Dr. Guaita recommended first the use of sublimate in strong doses; Sattler insisted upon the efficiency of scarifications combined with scraping of the granular tissues; while Manolescu suggested the use of the brush; but the value of the procedure depends upon the employment together of all these procedures, which individually are inefficacious, and upon the complete exposure of the superior cul-de-sac.

LOCAL AND GENERAL ANÆSTHESIA.

Grandclément (*Lyon Médical*, Nov. 12, 1891) states that local anæsthesia usually suffices for the performance of minor operations, such as the relief of ingrowing nails, opening of abscesses, enucleation of small, superficial tumors, or to overcome the circumscribed pain of inflammation or of neuralgia. Several methods have been proposed for the purpose, but all are not equally valuable or secure.

1. *Anæsthesia by congelation with the aid of a refrigerant mixture of salt and ice* was the only method used twenty-five or thirty years ago; to-day it is almost abandoned. It is painful and time-consuming, and is best applicable to the extremities, the toes or fingers, which can be plunged into the mixture. Besides, ice cannot always and everywhere be obtained.

2. *Spraying with ether* originated with Richardson twenty-five years ago. It is superior to freezing with ice; it requires a special apparatus and protracted application, and is sometimes quite painful.

3. *Spraying with ethyl chloride* has recently been recommended. Ten grammes of ethyl chloride contained in a small glass bulb, terminating in a capillary tube that has been sealed in the flame of a lamp, are vaporized by the heat of the hand (ethyl chloride vaporizes at +10° C. (50° F.). A fine spray escapes when the tube is broken. In a short time the area sprayed presents a white appearance and a degree of anæsthesia sufficient to open deep abscesses and to perform other minor operations.

4. *Hypodermatic injections of cocaine* induce phenomena of profound intoxication in certain individuals, even when small doses are employed. Unpleasant symptoms sometimes follow the instillation of cocaine into the conjunctival sac. In the violent periorbital neuralgias that are provoked by certain affections of the eye, Grandclément has obtained good results from injections of cocaine and antipyrine in association. He believes that the œdema and vascular stasis resulting from the injection prevent too rapid absorption of the cocaine. The same end is attained by applying an Esmarch bandage to the part before the injection of cocaine is made. Grandclément has observed that the anæsthesia produced by the mixture of cocaine and antipyrine persists for several days.

THE NATURE AND TREATMENT OF STAMMERING.

Emil Behnke (*Jour. Laryngology and Rhinology*, July, 1891) has recently declared that the terms stammer and stutter should indicate the same condition, rejecting a former distinction that stammer should refer to that form of obstruction in which there is inability to pronounce vowels, and stutter to that form of impediment in which the consonants are at fault. The causes of these disturbances are attributable to the nervous centres controlling the mechanism of respiration, phonation and articulation.

Children afflicted with stammering do not, as a rule, outgow the habit; ridicule or severity will increase the difficulty.

Conditions needing surgical or medical interference, such as spinal curvature, post-nasal adenoids, decayed teeth, intestinal worms and phimosis, may prevent cure of stammering until their removal.

Cases of stammerers are divided into two classes—those in which fault lies in management of respiratory apparatus, and those in which it does not. In the former the prognosis is more hopeful. To test patient, he is placed flat on his back upon a couch, and is drilled in methodized and graduated series of sounds and inspiration, produced by diaphragm and muscles of abdominal walls, the hand of the trainer upon the epigastrium accentuating these movements.

If, after such practice, the patient shows improvement, a favorable result may be expected from treatment. In those cases in which obstruction does not depend upon imperfect respiration, Behnke attributes much of trouble to "an involuntary exaggeration of all the stops and checks taking place in vocal apparatus from glottis to lips, and he must therefore be trained to make these closures as shortly and lightly as possible." Thus a short aspirate may be inserted after a consonant; as G-h-eorge, instead of George, or, as patient would say, G-g-g-eorge; and p-h-a, instead of pa.

Stammerers sing and whisper without difficulty, because in singing there is almost continued tone, and in whispering there is absence of tone. It is advised to dwell on vowels at expense of consonants—and if vowel difficult to sound, it should be preceded by a short inspiration. Another beneficial exercise is to speak slowly, with teeth overlapping and pressed tightly together.

Result of treatment influenced by severity of case, intelligence of patient, also existing morbid conditions, especially those due to chorea or other nervous disturbances.

SOME OBSERVATIONS ON THE USE OF PIPERAZINE.

Dr. Heubach, assistant in the Clinic of Prof. Zuelzer, in the Johanneum, Berlin, says, (*Internat. Centralblatt für die Physiologie u. Pathologie der Harn. u. Sexualorgane*) for several months back have been making trials with piperazine in their clinic and polyclinic. This base, which is readily soluble in water and strongly alkaline in solution, has the chemical formula $C_4H_{10}N_2$, and in constitution is a piperidin in which the CH_2 group has been replaced by the NH. It is now manufactured on a large scale (by the Chemische Fabrika. A., vorm. Shering, of Berlin) and has been therapeutically employed in various quarters, notably by Ebstein and Sprague, Vogt, Bardet and others.

By these observers the remedy was preferably tried in cases of gout, and also on patients in whom it was necessary to dissolve uric acid concretions in the kidneys (gravel and urinary calculus). The application was suggested by the fact that piperazine experimentally dissolved large quantities of uric acid in test tubes at 20° C. (68° F.); that the urate combination of piperazine, furthermore, was at least seven times more readily soluble than the hitherto therapeutically preëminent car-

bonate of lithium, and finally that the base, even in the presence of excess of uric acid, produced no acid but an easily soluble neutral salt.

Ebstein and Sprague furnish a table of results, produced on a patient with uric acid diathesis by seven days treatment, with increasing dosage of 1 to 3 gm. piperazine. This table gives the impression that the volume of urine was increased thereby; in one case the exhibition of 2 gm. of piperazine increased the volume from 1250 to 2160, and in another instance even to 2270 ccm. in 24 hours, while the sp. gr. was similarly reduced. In addition the acid reaction of the urine was considerably reduced, and in one case became alkaline. The uric acid, which, according to Vogt, is reduced in proportion with urea, does not show this action.

In collaboration with Dr. Kuh, he undertook a series of experiments, both of them taking at the same time, without change of regular diet, 2.5 gm. piperazine one day, 1 gm. the second, and 2 gm. the third day, dissolved in a glass of seltzer-water. Within two hours after taking the piperazine it could be found in the urine.

The urine was tested in separate portions, three taken during the day and during the night.

After administration of the largest dose, 2.5 gm., an inconsiderable increase of urine volume was noted in both persons —in one to 2260, and the other 1970, ccm. in 24 hours. The reaction always remained acid, and the specific gravity was not heightened. One gramme doses lowered the volume to a normal amount, 1630 and 1500 ccm., always acid.

The quantity of urine was not increased; the sp. gr. also continued within normal limits. The reaction of the urine, estimated alkalimetrically, was always acid, and approximately amounted to the normal, 2.29 with one, and with the other 1.75 g. HCl.

To determine the effect on metabolism they selected N. (nitrogen) and P_2O_5 (phosphoric acid). The nitrogen (resp. urea) showed no increase—resp. 11 and 10.8 in 24 hours; nor did the phosphoric acid, which amounted to 2.4 and 2.3 g. Consequently the relative amount of the latter continued normal, viz., 22.4 and 21.6.

Corresponding with this showing, the use of piperazine induced no disturbance in their general condition; but it must be noted that after taking the largest dose (2.5 gm.) both persons experienced very severe headache on the following morning, and in one vomiting occurred. The smaller doses of 1 gramme were taken regularly for several days consecutively without causing any derangement.

As regards the uric acid, a very small increase (0.78 and 0.49 g. in 24 hours) was shown in all cases.

A trial was made to see if urine containing piperazine would dissolve uric acid; the result, even at high temperature and with extended action, was decidedly negative.

The therapeutic trials which they then undertook yielded distinct success in two cases of lumbago; both were treated by subcutaneous injections of a 2 per cent. solution. Patients received 0.5 gm. doses four times daily, a total of 2.0 gm. in 24 hours. Improvement in conditions was noted on the third and fifth days, and on the ninth and tenth days both patients were free from pain. The injections, they state, were in themselves quite painful, but they did not cause abscesses, nor were they followed by unpleasant after-effects. For subsequent use of the remedy they prefer to use voluminously diluted solutions.

Piperazine deserves particular attention in uric acid concretions in the kidneys. They had opportunity to study two such cases in detail, and they proved remarkable, because of the exceedingly favorable results.

These two cases, in connection with the cases reported by Bardet, speak distinctly in favor of a specific effect of piperazine, and show the advantage and desirability of further therapeutic observation in this direction.

ACTION AND USES OF FILICIC ACID.

The isolation of the active principle of male fern has acquired toxicological interest of late, on account of the occurrence of several fatal cases of poisoning attending the therapeutic employment of the extract. The toxic properties of filicic acid are still disputed. It is uncertain whether filicic acid possesses toxic properties. Much, however, depends upon whether we employ the pure crystalline product or the crude precipitated acid. Herr Poulsson shows that these two modifications differ in their physiological and chemical relations; that there is but little doubt that the inactive crystalline body is an anhydride or lac-

tone of the amorphous filicic acid, and is better termed filicin. Filicic acid is well adapted for therapeutic purposes, as it is easily dissolved, held in solution in the intestines, and is only very slowly absorbed; thereby explaining how it effects the expulsion of parasites. These results explain why a freshly-made extract of male fern is more active than in older preparations.—*The Pharm. Journ. and Trans.*, p. 85, August 1, 1891.

HYPNOTISM.

In a paper read before the Colorado State Medical Society, Eskridge (*New York Medical Journal*, August 1, 1891) stated that hypnotism is real and subjective and not dependent upon any mysterious influence of the hypnotist over the subject. The therapeutic value of hypnotism is governed by the mental impressions made during hypnosis, a state of increased impressionability. Much that is accomplished by hypnotism may be accomplished by repeated impressions without hypnosis. Hypnotism carries with it certain dangers to the hypnotist, to the subject and to the community, to be obviated by proper precautions. It remains to be determined whether or not the therapeutic value of hypnotism is greater than the unavoidable dangers of its application. The practice of hypnotism should be under state control and restricted to physicians and other scientific investigators.

MEDICINE.

ACTION OF UREA ON THE VASCULAR WALLS.

Dr. Munk, several years ago, on perfusing blood to which urea was added through a surviving kidney, found that the addition of urea accelerated the blood stream, and increased the secretion from the kidneys. This result was also produced by sodic chloride, the sulphates and phosphates of the alkalies, creatin, sugar, creatinin and other substances. The vaso-dilator action of the urea on the kidneys was not due to the action of the urea on the central nervous system, for it occurred in the excised and still living kidney. Cavazzani and Rebustello have made somewhat similar experiments by perfusing blood mixed with urea through several organs, but in all cases the organs or parts were left *in situ*. The fluid perfused was 1 part of bullock's blood mixed with 2 parts of normal saline solution (0.75 per cent. common salt). The animals employed were dogs, cats and rabbits. The quantity of urea added to the blood varied from 0.5 per cent. to eight per cent. as a maximum. Urea possesses a marked vaso-dilator action not only on the blood vessels of the kidney, bnt also on the vessels of the brain, liver and musculo-cutaneous vessels in the last case, as shown by its action on the blood vessels of the hind limbs. Speaking generally, the vaso-dilator action of urea is directly proportional to the quantity per cent. of urea present in the blood. The minimum percentage of urea required to cause vaso-dilatation is for the kidneys 0.5 per cent. and for the other organs mentioned one per cent. In opposition to Munk, the authors have never observed a secretion of true urine during their experiments.—*British Medical Journal.*

DISORDERS CAUSED BY TRICOCEPHALUS DISPAR.

Dr. Moosbrugger (*Jahr. f. Kindhlkde*, xxxiii, p. 137, from *Württemberg med. Correspondzbl.*) questions the usually accepted statement that tricocephalus dispar does not cause symptoms. He has found four recorded cases in which serious nervous symptoms were attributed to it, and adds a fifth case, a boy, aged 1½ years, who for six months had had diarrhœa of gelatinous slimy stools (sometimes blood-stained), had suffered from spasmodic cramps of the arms and legs, and had deteriorated very much in general health. The presence of progressive anæmia suggested the possibility that the child might be the host of anchylostoma duodenale; an examination of the fæces, however, showed the presence of the eggs of tricocephalus dispar in such enormous numbers that Professor Leichtenstern calculated that the child was passing about 3,000,000 eggs with its stools every twenty-four hours; he further calculated that to yield this number of eggs there must have been from 1,000 to 2,000 female worms in the child's intestines. Treatment by santonin, calomel, male fern, dry clysters of garlic, tobacco, yellow iodide of mercury, and decoction of pomegranate, met with little success, only two worms (one male and one female) being expelled. However, during a severe attack of feverish bron-

chitis they were passed spontaneously in large numbers. Their injurious effect on the host is to be attributed in part to abstraction of blood and serum, and partly to reflex irritation. Infection is believed to take place usually by the ingestion of imperfectly cleansed vegetables, but in this case the child was in the habit of sucking and swallowing garden soil.—*Brit. Med. Jour.*

KERAUNO-NEUROSES.

Frankl-Hochwart (*Zeitschr. f. klin. Medicin*, Bd. xix, H. 5 u. 6, 1891) describes as kerauno-neurosis a condition that develops in persons who have been struck by lightning. The symptoms are those characteristic of the traumatic neuroses, and include palsies, tremor, derangement of common and of special sensation, limitation of the visual fields, ataxia and exaggerated reflexes.

SPASTIC INFANTILE SPINAL PARALYSIS.

Dr. Pierre Marie (*Gazzetta dégli Ospitali*, No. 57, 1891) thinks the prognosis not absolutely unfavorable; an amelioration may take place in three to ten years. A certain degree of rigidity will always persist. Regular and non-violent massage, using large, passive movements, warm baths and galvanizations of the medulla, are the most efficacious means known.

THE SPECIFIC GRAVITY OF THE BLOOD IN HEALTH AND IN DISEASE.

As a result of a series of fifty-four observations in conditions of great diversity, Siegl (*Wiener klin. Wochenschr.*, iv, 33, 1891) has arrived at the following conclusions:

1. The specific gravity of the blood is dependent upon the proportion of hæmoglobin and is independent of the number of blood-cells.

2. Diseases, acute as well as chronic, only affect the specific gravity of the blood when they have led to gradual prostration. Rapid loss of strength, on the contrary, appears to exert but little influence. In the course of diseases in which the blood is contaminated by the products of pathological tissue metamorphosis, or in which the blood is deficient in its normal chemical constituents, there is, in addition to an absolute change in the specific gravity, a disproportion between the specific gravity and the percentage of hæmoglobin. In hepatogenous jaundice, in diseases of the lungs or of the heart attended with cyanosis, in diseases attended with loss of bodily fluids, the specific gravity is (relatively to the percentage of hæmoglobin) raised. When the blood is deprived of albumen as a result of albuminuria, and probably of long-continued suppurative processes, the specific gravity is lowered. In renal disease the quantity of urine and the degree of albuminuria will in each case indicate how far hydræmia or hypalbuminosis is responsible for the abnormal specific gravity.

3. In cases of anæmia, in which there is no organic disease that exerts an influence upon the specific gravity of the blood, this constitutes an index of improvement or of progression as regards the anæmia.

THE INFLUENCE OF DISEASES UPON THE RESPIRATORY INTERCHANGE OF GASES.

To determine if disturbances involving the exchange of gases between the air and the blood, and if anomalies of tissue metamorphosis in conjunction with which the need of oxygen or the capability of the tissues to unite with oxygen may be altered, do in reality materially influence the respiratory interchange of gases, Kraus and Chvostek (*Wiener klin. Wochenschr.*, Bd. iv, 1891, p. 33) made forty observations in twelve persons with various forms of anæmia (pernicious and secondary anæmia and chlorosis), leukæmia, and the carcinomatous cachexia. Under ordinary conditions no aberration from the normal was observed in the gaseous interchange. The taking of nourishment invariably augmented the interchange, as happens also in healthy persons during digestion. In a small number of cases muscular activity increased the combustion of oxygen and the production of carbonic acid, but not in the same degree as in health; in the anæmic patients, the respiratory coefficient (which normally arises) was lowered.

To determine the activity of the bodily oxidation, benzole was administered to six patients with diabetes, anæmia, carcinoma of the stomach, and leukæmia, and the quantity of phenol excreted was measured. The proportion of phenol was found small in conditions of impaired

nutrition, but no special change was observed for any single affection.

In investigating the influence exerted upon the respiratory process by an increased volume of oxygen in the inspired air, an admixture of ten volumes of nitrogen and ninety volumes of oxygen was used. The subjective condition of healthy and ill persons was not materially influenced by the continuous breathing of such a mixture; nor did objective manifestations appear. During the first ten minutes of easy breathing a considerable increase in the comparative quantity of oxygen absorbed was noted; subsequently the absorption of oxygen fell to the normal or lower. That this primary increase took place in anæmic patients with a decided deficiency of hæmoglobin makes it evident that the excess of oxygen taken up combines with the tissues. For a short time at the beginning of the experiment the exhalation of carbonic acid was increased, though not in the same degree as the absorption of oxygen. These observations indicate that there is no more substantial basis for the employment of oxygen in disease than has hitherto existed. Clinically, inhalations of oxygen were inefficacious. The most important indication for such a measure would be the sudden occurrence of respiratory insufficiency.—*Amer. Jour. Med. Sci.*

EPILEPTIC AUTOMATISM.

In a recent number of the *Revue Médicale de la Suisse Romande*, Dr. Grandjean has related a case of very great interest. It is that of a man of thirty-four, who, with the exception of an attack of somnambulism at the age of eight—an attack in which he had walked into his father's bedroom and congratulated him on being elected king of Italy—had been previously healthy. Towards the end of January, 1890, he began to suffer from nightmare and depression, without apparent cause, but he had no headache or vomiting. This condition persisted for two weeks. Then, on Feb. 9th, after going to his office and working as usual, at nine o'clock in the morning he took his hat, set out on foot, and arrived at Payerne, a village fifty kilometres distant. He had no recollection of anything that happened from the time he left his office until he awoke, in the middle of the night, in an inn at Payerne. His boots, he found, were much worn, but his clothes were in good order. He presented none of the usual effects of having passed through an epileptic paroxysm, except that he had a violent headache. After this he remained as usual for seven months, except that he had occasional "absences." Thus, on one occasion, while writing, he was surprised to find that he had continued at his work for an hour without any recollection of having done so. The work was done perfectly, without a single mistake. At the end of the seven months he had another attack similar to the first, but lasting for two days, during which he had gone about to different places acting in a manner which did not strike any observer as strange or peculiar, but being all the time unconscious. Five months later he had a similar, even more elaborate, attack, which also lasted for two days, and was followed by headache more violent than usual. Dr. Grandjean comes to the conclusion that this is undoubtedly a case of epileptic automatism. He does so from the nature of the attacks, from the fact that the man also suffered from "absences" of longer or shorter duration, really attacks of *petit mal*, and because the latter became almost totally suppressed under treatment by the bromides. The case is an important one, and it should serve to impress the fact once more that some criminals who profess complete unconsciousness of the act or acts with which they are charged may really be the subjects of epileptic automatism. If this patient had committed some crime during one of those periods of unconsciousness, a defence to the effect that he was the subject of epilepsy would have been received with considerable doubt, especially as there was nothing in the nature of a severe fit to point to in the former history, but only those temporary "absences" without any obvious convulsion.—*Lancet.*

STERILIZATION OF BRUSHES.

These are boiled for five minutes in the soda solution and kept ready for use, floating in sublimate solution, 1 to 2,000 (sublimate and acetic acid equal parts), with the bristles down in a small, enamelled, water-tight box, devised by Von Bergmann. In the operating-room the solution is changed two or three times daily.—*Uni. Med. Mag.*

A CONTRIBUTION TO THE PATHOLOGICAL ANATOMY OF THE RETINA AND OPTIC NERVE IN DISEASES OF THE BRAIN AND ITS MEMBRANES.

In the laboratory of Prof. Iwanski, the author has examined the retina and optic nerve in purulent basilar meningitis, 7 cases; tuberculous meningitis, 4 cases; chronic meningitis, 12 cases; hæmorrhage of the brain, 7 cases; and arterio-sclerosis of the brain, 9 cases, and has determined the following facts, viz.:

1. All diseases of the brain and of its membranes in consequence of injuries inflicted upon them, induce pathological changes in the retina and optic nerve.

2. Acute inflammation of the meninges occasions œdema of the papilla and disturbances which are intimately associated with the chief causes of this latter and the retina. (Neuro-retinitis œdematosa.)

3. Chronic inflammations of the meninges produce the same condition in the retina.

4. Arterio-sclerosis of the cerebral vessels extends also to the papilla and the retina, and always induces peripheral œdema in the latter. The œdema is the result of chronic venous hyperæmia, which is occasioned by disturbances in the circulation of the blood.

5. When extravasation follows arterio-sclerosis, this phenomenon can usually be observed also in the vessels of the retina.

6. In consequence of the pressure, which the accumulated mass of exudation exerts upon the optic nerve entrance, choked disc (staungspapilla) very frequently results.—Falser, *Deutsch. Med. Zeit.*

SURGERY.

REMOVAL OF SARCOMA OF THE MESENTERY.

A case has been lately recorded by Professor Llobet, of Buenos Ayres (*Revue de Chirurgie*, August, 1891), in which he removed with complete success a sarcomatous tumor of the mesentery, and at the same time resected a portion of the small intestine almost 5 feet in length. The patient, a man aged 23, whilst under treatment for urethral stricture, was found, quite by accident, to be affected with a very movable hard tumor of about the size of the kidney, which was situated within the abdominal cavity in the middle line, and about two inches below the umbilicus. The existence of this growth had not been previously suspected by the patient, who asserted that he had not at any time suffered from symptoms of disturbed digestion, or from pain in the abdomen. The growth was free from tenderness, save on forcible compression. In his endeavor to diagnose the nature of this morbid condition, the author was lead to reject the idea of a floating kidney by reason of the absence of urinary troubles, and of the free lateral mobility of the growth, and, guided by the facts of the situation of the swelling in the middle line, and of the absence of pain and of both general and local disturbance, he was disposed to regard it as a tumor of the mesentery. At the end of 1890 laparotomy was performed for the removal of the growth. A globular tumor was exposed involving both layers of the mesentery, and covered in front by a long loop of small intestine. The portion of mesentery between the tumor and the intestine was traversed by numerous large blood vessels. It was thought to be necessary to remove with the tumor the portion of small intestine adhering to its anterior surface. Its retention in the abdominal cavity after dissection from the tumor would, it is held, have exposed the patient to the almost certain danger of relapse and of wide and general diffusion of the disease, and, moreover, the retained portion of intestine would very probably have become gangrenous as a result of removal of the corresponding portion of mesentery, and of arrest of the vascular supply. After a thick ligature of catgut had been applied to the portion of mesentery attached to the tumor, the fixed portion of intestine, the length of which measured one metre and a half, was resected, and the two open ends of the divided intestine were brought together by sutures arranged in two layers, one set being carried through the mucous coat, and the other set through the muscular and serous coats. The tumor was then excised by means of curved scissors, the bleeding being arrested by the application of the thermocautery. The operation, which was performed with strict attention to all antiseptic precautions, lasted two hours and a half. The patient, who was able to get up and sit in a chair on the fifteenth day from the date of the operation, made a good recovery. The resected

portion of intestine which had been taken from the distal part of the ileum contained a round worm. No description is given in this paper of the minute structure of the growth. Professor Llobet draws from the facts of the case the following conclusions: (1) Whenever a diagnosis has been made of sarcoma or fibro-sarcoma of the mesentery, the surgeon, unless the growth has attained very great dimensions, should resort to extirpation; (2) the operation should be performed as soon as possible, and before the tumor has become very large; it is then less serious, and there is less probability of subsequent generalization of the disease and of its local recurrence; (3) in cases in which the diagnosis is doubtful, the surgeon should perform an exploratory laparotomy; (4) if the intestine be found adherent, even over a considerable extent, there should be no hesitation in performing enterectomy; (5) resection of a considerable length of small intestine is attended with the less risk the further the resected portion of intestine is away from the stomach.—*Brit. Med. Jour.*

RADICAL CURE FOR OZÆNA.

Dr. Michel Christovitch, of Salonique, says that ozæna is considered as an incurable disease, simply because its treatment was exclusively symptomatic, struggling against the stagnation and fetidness of matters by means of irrigations, of antiseptic pulverizations, etc., . . . the disease being considered as originating from a strumous or specific constitutional general state.

It was only three years ago that the French Society of Laryngology, in Paris, discussed at length the nature of ozæna, and came to the conclusion that it is merely local and of a microbian origin.

Hajet has found, in the secretions of ozæna, a coccus very similiar to the capsulated coccus of Friedlander. That bacillus decomposes organic matters; then fatty acids are developed, producing the fetidness characteristic of ozæna. The microbe resides in the glands of the nasal mucous membrane, which are media propitious for the culture of that microorganism.

Ozæna, therefore, may be cured when the glands of the nasal mucous membrane disappear, either by the effects of the disease itself, or through an operation.

Ozæna is only the characteristic symptom of the disease called chronic atrophic rhinitis.

That atrophic rhinitis will develop better with a person of a weak or strumous constitution, but well constituted individuals are not exempt.

Basing myself on the anatomo-pathological lesions, I find that the most rational treatment is by destroying the focuses of microbes—that is, the degenerated mucous glands—and, according to the more or less advanced state of the affection the surgical treatment shall be more or less energetic. At the start of the affection we should limit ourselves to the cauterization of the deep and superior parts of the nostrils with the galvano-cautery, and repeat it according to circumstances. When the lesions of the atrophic rhinitis are already advanced, it is absolutely necessary to practice the real operation in destroying, by removal, all the degenerated mucous glands covering the *nares internæ* up to the naso-pharyngeal region. Then, in order to complete the operation, we cauterize with the galvano-cautery.

Process of Operating.—On the day preceding the operation we make abundant alkaline and antiseptic irrigations of the nostrils, which means are insufficient for a complete antisepsy and for removing the concrete matters, which are very adhesive, especially toward the superior anfractuosities. We render the field of operation less sensitive, by means of pads of hydrophile cotton dipped in a concentrated solution of cocaine, which are introduded high enough and deeply.

After ten minutes, we withdraw the pads, and we proceed with the operation. With a scraper elongated and of small dimension, so that it may be easily introduced, even into the small anfractuosities, we scrape and empty effectually and rapidly all the degenerated nasal mucous membrane covered with concrete masses, even to the naso-pharyngeal region, and we continue scraping in this way until the fetidness has completely disappeared. After the scraping we immediately make the cauterization of the profound parts that have escaped scraping. The hæmorrhage, that is considerable, stops rapidly by the introduction, into the nostrils, of the pads of hydrophile cotton in a large quantity.

One single operation well made suffices, in most cases, for the complete cure.

That operation presents no inconvenience, except some pains in the ears.

In one case, the consecutive treatment consisted simply in snuffing powder of iodoform mingled with powder of boric acid.

In conclusion, the efficacious treatment should be local and, in the second place, general. Ozæna should be treated early, not only in order to stop the progress of the affection, but also in order to prevent the very grievous consequences resulting from the continual inspiration of the nasal putrid matters.

THE SEAT OF PUNCTURE IN PARACENTESIS ABDOMINIS.

Trzebicky (*Archiv. für klin. Chir.*, xli., 4), in performing paracentesis abdominis at the point of election—that is, midway between the umbilicus and the anterior superior spine of the ilium—wounded a large blood-vessel which gave such troublesome bleeding that the life of the patient was threatened. The hæmorrhage was arrested by compression of the common iliac artery. Incited by this experience, and by several reports of fatal bleeding following puncture at this point, Trzebicky conducted an experimental research upon a large number of cadavers. As a result of this he announces the following conclusions :

In the majority of cases paracentesis performed at a point midway between the umbilicus and the anterior superior spinous process of the ilium is perfectly safe, since neither the epigastric artery nor any large branch of this vessel is liable to be wounded. The artery commonly crosses this line at the junction of the inner with the middle third.

In a certain proportion of cases, however, the epigastric artery or one of its branches lies directly beneath the point of election.

The course of the epigastric artery is seldom exactly similar in the two sides of the body.

Since the artery runs within the sheath of the rectus muscle, its course depends mainly upon the position of this muscle. In case the two recti are separated by abdominal distention, the artery is displaced, so that it lies very near the point of election for puncture. The rectus muscle does not, however, bear a constant relation to the artery. At times, even though the muscle is displaced to the side, the artery lies near the middle line.

Variations in the origin of the epigastric artery seem to have no influence on the course of the former vessel.

The artery is usually accompanied by a single vein.

Paracentesis abdominis should be performed either in the linea alba or in the outer half of the line joining the umbilicus and anterior superior iliac spine. In case the linea alba is selected, it is not important to keep strictly in the middle line, since there is an arterial branch which may be wounded if the trocar is entered, even slightly, to one side.—*Am. Jour. of the Medical Science.*

OBSTETRICS.

THE TREATMENT OF ALBUMINURIA AND NEPHRITIS IN PREGNANCY.

Mijulieff (*Geneesk. Cour.*, 1891, No. 18) has derived the following indications for treatment from three cases of nephritis in pregnancy in which the fœtus perished in the uterus : when a woman previously healthy shows symptoms of nephritis during the first months of pregnancy, abortion should be induced ; in the second half of pregnancy, it is rarely necessary to interrupt pregnancy, except for urgent symptoms. In chronic nephritis during pregnancy, labor should be induced in the interest of mother and child as soon as viability is possible.

OPIUM ENEMATA IN THREATENED ABORTION.

In the *Gazeta Lakarsks*, No. 33, 1891, p. 657, Mr. Feliks Arnstein, of Kutno, Russian Poland, maintains that in case of threatened abortion the practitioner is justified in accelerating and terminating the process only when the interruption of gestation is induced by death of the fœtus. "In all these cases" he says, "be the uterine pains of short or long standing, weak or strong ; be flooding absent or present, scanty or profuse ; be the cervix softened or not, and the os closed or widely gaping—in all alike treatment must consist in adopting all possible measures for retaining the ovum in the womb and arresting its threatened expulsion therefrom." As far as the writer's personal experience goes, the best way to accomplish this is the persevering administration of opium *per rectum*. As much as 15 drops of simple tincture of opium, *Ph. Ross.* (containing 1 in 10 of the drug) with 2 tablespoonfuls of lukewarm water should be injected into

the bowel every hour, the patient lying quietly in bed and taking occasionally some acid drink. Leaving out of consideration cases in which complete detachment of the ovum has already taken place, the treatment is said to be followed by the best possible results: "the uterine pains steadily and fairly quickly become less intense and less frequent, and ultimately cease altogether; hemorrhage becomes less and disappears; in some (occasionally twenty) hours the os is found to have contracted and the ovum to have receded." The author relates a case in which a fairly advanced abortion was controlled by the injection of 45 drops of the opium tincture. In some cases, however, the total quantity required for the purpose may amount to 80 or over 100 drops. Pregnant women are thought to tolerate opium much better than other persons, the toxic effects being usually limited to a heavy feeling about the head, and drowsiness, which disappear in a day or so.—*British Med. Journal.*

OBSTETRICAL PARALYSES IN THE NEWBORN.

Dr. Danchez (*Annales de Gynéc. et d'Obstét.*, October, 1891) concludes a series of observations upon injuries to the child during labor, and their more or less permanent effects. A number of instructive cases have beed collected and published in abstract in Dr. Danchez's memoir. In several, pressure on Erb's point (where the fifth or sixth cervical nerves emerge) caused more or less paralysis of the deltoid, brachialis anticus, biceps, and supinator longus. This pressure is made by the obstetrician's fingers during version, and traction on the shoulders during extraction in breech cases, and in normal presentations where the second stage is lingering. Sometimes the serratus magnus is paralysed. The forceps may do as much harm as the fingers. A bad case of dislocation of the shoulders and paralysis, under Dr. Monnier's care, is published for the first time by Dr. Danchez. A country midwife undertook a breech case. In order to hasten delivery she dragged the child's body forcibly by the feet. The arms were thus pulled over the head. Next day it was noticed that the child's arms were abducted and rotated inwards. When the child was seen four years later by Dr. Monnier the arms remained in that position. When it was eleven days old a physician at Quimperlé diagnosed dislocation of both shoulders, but did not, apparently, attempt to reduce them. Electricity was tried for six months by another practitioner. When examined by Dr. Monnier the dislocations were evident. All the muscles of the shoulder were atrophied; the teres minor and infraspinatus formed a firm cord. The child could hardly use his hands. He was a male in good general health. Sensibility was intact all over the damaged upper extremities. Dr. Danchez distinguished two classes of congenital obstetrical paralyses. The first class includes the so-called spontaneous paralyses, when the lesion is entirely due to the natural or abnormal mechanism of labor, and not to the obstetrician or his instruments. The head or one of the limbs is pressed against the surrounding parts to the damage of certain nerves. The second variety bears the term "traumatic paralysis," where during traction, version, or the use of the forceps, some damage is done to a nerve or to a plexus of nerves. Over and above these two classes Dr. Danchez adds a third, which he terms "obstetrical pesudo-paralysis," where the paralysis is simulated by primary or secondary dislocation of one or both upper extremities, as in Dr. Monnier's case. Obstetrical paralyses are almost entirely motor. Nevertheless, two cases are recorded where sensory paralysis followed difficult version; the serratus magnus and many muscles in the arm were, in both instances, paralyzed.—*British Med. Journal.*

PILOCARPINE IN PUERPERAL ECLAMPSIA.

In the *Gazette hebdomadaire des sciences médicales* for September 12, Dr. Strisover adds to the experience of observers in this field the results of his use of pilocarpine in the treatment of eclampsia. By the subcutaneous injection of hydrochloride of pilocarpine the author has been successful in controlling the convulsions and preventing their recurrence in ten cases. The treating successively of such a number of cases without one death has led the author to the conclusion that pilocarpine is an antagonist to the eclamptic process; that feebleness of the pulse is not a contra-indication to the repeated injection of the drug, so long

as the convulsions reappear; and, finally, that the condition of the pupils is to be relied upon as an index to the further accession of the convulsions or to immunity by the physiological action of the drug.

GYNÆCOLOGY.

HYDATIDS IN THE PELVIS SIMULATING OVARIAN TUMOR.

Dr. Olenin (*Nouvelles Arch. d'Obstét. et de Gynéc.*, Supplement, September, 1891, p. 426) read before a Russian Medical Society a remarkable case of erroneous diagnosis. A multipara, aged 43, had a swelling with pain in the hypogastrium for two years. Abdominal section was performed and no ovarian tumor could be found, but innumerable hydatid cysts were disseminated in the usual manner over the omentum, and also in the substance of the liver. The largest of all the hydatids, a cyst as big as a child's head, was situated in the pelvis. The patient died of peritonitis on the day after operation.—*Brit. Med. Jour.*

THE DIAGNOSIS OF CHANCRES OF THE CERVIX.

According to Rasumow (*Moskau*, 1890) in the primary affection of the cervix appears in two varieties—as erosive and ulcerative, and deep chancres having sharply defined borders. The author claims that the diagnosis of primary syphilitic affection of the portio vaginalis is not as difficult as is claimed by most gynæcologists. It is made evident by the presence of indolent, hard, and immovable glands in the inguinal region. Soft ulcers of the cervix may often be overlooked, being painless and manifesting no symptoms. Rarely an inguinal bubo develops in connection with a soft chancre of the portio vaginalis.

DANGER OF CAUTERIZATION OF THE CERVIX AND UTERUS.

Dr. R. Pichevin (*Nouv. Arch. d'Obstét. et de Gynéc.*, February to August, 1891) has published a valuable series of cases, collected from numerous sources, which show the danger of lavish and careless use of caustics—a danger common to all the resources of "minor gynæcology" when employed in an unintelligent manner. Dr. Pichevin refers chiefly to mineral caustics, such as chloride of zinc in sticks, *pâte de Canquoin*, and nitrate of silver. The latter is by no means harmless. Dr. Walton describes three cases where complete atresia of the cervix with amenorrhœa followed the application of sticks of nitrate of silver to the interior of the uterus. Forcible dilatation of the cervix was found necessary. In other cases disease of the appendages followed frequent cauterization. — *Brit. Med. Jour.*

TOTAL EXTIRPATION OF THE UTERUS.

Kattenbach has totally removed the uterus 57 times—53 times for carcinoma, twice for sarcoma, twice for prolapsus. He finds that total extirpation is always indicated when the *technique* of the operation can be easily executed. He even hopes to attain a complete cure. Theoretically, partial extirpation may be excellent and sufficient, but practically, it is very rarely indicated. For example, he partially removed the uterus of a woman seven months pregnant, upon the anterior lip of which he found a carcinomatous growth as large as a walnut. He removed it by a triangular incision, and the pregnancy continued its normal course. Generally speaking, he is of the opinion that whenever it is necessary to extend the operation beyond the vaginal insertion entire removal of the organ is to be preferred, as there is much greater danger of relapse in cases of partial resection. Of the 57 cases of total extirpation only 2 died. One of these deaths was caused by uræmia from ligature of the left ureter, and also, perhaps, by an injury to the bladder. One of the dangers of the operation is the possible wounding of the ureters or the bladder. In two cases he was afterwards obliged to perform colpocleisis, on account of vesico-vaginal fistula. Three of the women in question were over 60 years of age, and grave pulmonary affections afterwards supervened; but they had previously suffered from bronchitis, emphysema and cardiac weakness. He attaches great importance to the suture of the peritoneum and to means of disinfection, and prefers solutions of boric and salicylic acid. As to the danger of relapse, a year had passed away without the reappearance of the disease, in 25 of the cases of carcinoma, and a still longer period in 7 others. All the patients recovered

promptly after the operation. In case of relapse, subsequent treatment is by the use of Paquelin's cautery and chloride of zinc. He never had abundant hæmorrhage. One patient was cured of a carcinomatous fistula of the bladder by the operation. As a whole the results of his work encourage total extirpation of the uterus, especially when it can be performed at a favorable moment.—*Journal de Médecine de Paris*, Sept. 20, 1891.

LAPAROTOMY IN PERITONITIS.

Dr. Krecke, of Munich, has collected from various sources the results of laparotomy in diffuse purulent peritonitis, and points out that the operation has been the means of saving many lives; for, although the statistics of peritonitis treated medically show a mortality considerably below that given by laparotomy, it is clear, as he says, that a large majority of the successful cases in the first category are such as would never be submitted to surgical treatment, many of them being referable to inflammatory lesions of the female pelvic organs, and not of an infective kind. Surgical intervention is, on the other hand, called for in case of general infective peritonitis, such as arises from perforation or in the puerperal period, or from extension of suppuration from other parts. Dr. Krecke points out the difficulties of securing effective drainage, and is averse to irrigation, owing to the possibility of its disseminating septic material to parts of the membrane not previously infected, or of exciting hemorrhage. He prefers rather a simple incision, drainage, and the use of iodoform gauze. Peritonitis is fatal from septicæmia, due to the absorption of poison from the cavity; but it is remarkable how tolerant the membrane may be of such virus. If the limit of this tolerance could be gauged, some guidance might be obtained as to the appropriateness of surgical interference in any case. But the fact is that there are various degrees and forms of acute peritonitis, some being fatal from sceptic absorption within a few hours of the onset, before even any noticeable change takes place in the membrane itself. Early operation is then called for, and consideration must also be had to the source of the inflammation. Dr. Krecke's statistics are interesting and instructive. He has collected 119 cases of laparotomy in general peritonitis, the origin of which was determined in all but 18, of which 9 were successfully treated by laparotomy and 9 died. The majority of the remaining 101 cases belonged to the category of perforation peritonitis. Of these, 36 were cases of general peritonitis following perforation of the vermiform appendix; 12 were cases of typhoid perforation (a condition which at first sight it might seem hopeless to deal with), and these yielded 5 successes; 12 were due to perforation from gangrene and other causes implicating the bowels —of the gangrenous not one recovered, and of the 8 others only 3 were cured by the operation. No case of perforating ulcer of the stomach has yet been saved by laparotomy—a result precisely the same as that yielded by medical treatment. Of traumatic cases, 3 of punctured wounds and 1 of gunshot were recovered; but of contusions, only 3 out of 8 cases recovered from laparotomy. The measure, however, saved 5 out of 13 cases of puerperal peritonitis. Lastly, a group of cases of peritonitis from various other causes gave 3 deaths and 6 recoveries. The total result is 119 cases of general peritonitis treated by laparotomy, 51 recoveries, and 68 deaths—statistics which are certainly encouraging.—*Lancet.*

HYGIENE.

SOME COMMON ERRORS IN THE FEEDING OF YOUNG CHILDREN.

In a recent lecture reported in the *Practitioner* for July, Dr. Cheadle draws attention to certain points in the feeding of infants in regard to which faulty and injurious practices prevail. One of the most frequent sources of disaster is the sudden weaning with the use of fresh cows' milk and water. The massive curds formed from cows' milk are frequently beyond the feeble digestive powers of the infant. Dilution will partially remedy the matter, but cannot, as a rule, be carried to a sufficient extent without unduly increasing the bulk of the food. The clots, by decomposing, cause colic, vomiting and diarrhœa. Boiled milk not only is to a certain degree sterilized, but clots less firmly than raw milk. Children should be weaned on boiled milk and barley water. In the case of very young or delicate children, however, the milk should always be peptonized at first, a proper degree of dilution being observed at the same time.

There is danger here of another grave error—the prolonged use of artificially-digested foods. While these preparations do excellent service in the case of children just weaned or with small digestive power, they are not proper for continued use. The power of digesting casein becomes gradually less, nutrition is impaired, and the child tends to become flabby, anæmic and soft in bone. Still another error consists in the furnishing of an insufficient gross amount of nutritive material. A child may be unable to digest a mixture of milk unless highly diluted, but the capacity of the stomach being limited, it may be impossible for it to take a sufficient quantity of such a mixture to supply the material required for growth and nutrition. The difficulty may be overcome by the addition of cream or some good preparation of meat juice, the quantity of milk being increased as the digestive power develops. Food deficient in fat, as well as that deficient in protein, is certain to cause trouble. Fat especially is of great importance in the food of young children. Those deprived of these two elements are often large and fat, but flabby, anæmic and rachitic; yet most of the artificial foods upon which children are so largely fed are almost wholly lacking in fat and to a less degree in proteids. The presence of an antiscorbutic element in the food is also a matter of prime importance. Fresh milk contains the element in sufficient quantity, but all farinaceous foods, and all the dry artificial foods, are decidedly deficient in this regard. They require the addition of some fresh element to supply the antiscorbutic quality.—*N. Y. Med. Jour.*

VEGETABLE BUTTER.

F. Jean states that an alimentary fat has been manufactured at Mannheim from the oils of the kernel of the cocoanut (*Cocos nucifera*). A hectare of cocoa palms, representing 225 trees, yields yearly 800 kg. of oil. Hitherto the use of these oils has been hindered by their acrid flavor; but by treatment with alcohol and animal charcoal the rancid flavor is removed and the product is rendered white. This is the only fat which is analagous to the cow's butter, as it contains the same proportion of soluble fats. It has the advantage of containing no pathogenic germs.

HOW TO JUDGE THE QUALITY OF CONDENSED MILK.

The general appearance when poured from a spoon should be glossy; the more glossy the better. It should be ropy or stringy like very heavy syrup.

The color should be that of cream, but the color varies according to the season of the year in which the milk is condensed, the same as milk not condensed varies in color. Milk is more yellow in summer, when cows are on pasture, than in winter, when they are fed on dry hay.

Thickness varies with age. Thickening by age is natural to condensed milk; rapid thickening only proves that the milk is preserved in the best manner, and that it retains in the highest degree the characteristics of milk in its natural state. Condensed milk which does not thicken by age, or which thickens very slowly, is milk abused in the process of condensing. Consumers make a great mistake in supposing that the thinnest condensed milk is the best. The thinnest condensed milk contains the most water, and, of course, less of milk solids or nutritives. The thickest condensed milk, if in sound condition, is the most valuable. There is a degree of thickness, however, that is inconvenient. If condensed milk is so thick that it will not run out when an open can is inverted, it is troublesome to dissolve. If it is not actually hard, very little stirring in the can will render it sufficiently liquid for convenient use.

Condensed milk, if properly done, does not destroy cream globules, but leaves the constituents of milk unaltered and natural. One method, therefore, of determining the relative quality of different samples of condensed milk is to ascertain the amount of butter that can be made from each.—*Scientific American.*

ALCOHOL AND THE NERVOUS SYSTEM.

In the inaugural dissertation of Dr. Spaink, of Baarn, of which a short abstract appears in the *Neurologisches Centralblatt*, an account is given of the results of certain experiments carried out with the view of testing the effect of alcohol on the peripheral nervous mechanism of rabbits. Clinically, it was found that the animals lost weight, became dull and weak, had tremor of tongue and shaking all over, and finally lapsed into a condition closely resembling delirium tremens. In the peripheral nerves examined there

was found to be the usual degeneration of the medullary sheath, but there was also present a curious corkscrew or even knotted appearance of the axis cylinders, which does not seem to have been previously described. The author regards the appearance as pathological, and not due to the methods of hardening or staining.—*Lancet.*

PÆDIATRICS.

NOCTURNAL ENURESIS IN MOUTH-BREATHERS.

Dr. Otto Koerner says that a very common cause of enuresis in children is the habit of mouth-breathing, and reports some cases in support of this view in the *Centralblatt für Klinische Medicin* for June 6, 1891. In every case of wetting of the bed by children, the physician, he says, ought to examine the little patient carefully to see whether there is any obstruction in the upper respiratory passages, and even if none be found the child should be observed when sleeping to see if it is not breathing through the mouth.

RAISING CHILDREN IN BRAN.

This method was proposed by M. Pue at the *Société Normande d'Hygiene Pratique*. It consists of a cradle which has the wooden bottom taken out, and is then lined with a strong cloth. In this is placed sterilized bran to nearly half a yard in depth. A hair pillow is used. The baby has only a short flannel shirt on and is naked from the navel downward. It is covered with a woolen blanket, and a wool-lined dress is kept to put it in when taken up for nursing. It has thus full liberty of movement in all its limbs, while its dejections pass at once into the pure bran, keeping the child dry and clean, even if there is diarrhœa. This method is a cheap one, the bran not costing as much as diapers.

INTUBATION IN CROUP.

Escherish (*Rev. Mens. des Mal. de l'Enf.*, April, 1891), after discussing the advantages and disadvantages of tracheotomy and intubation, and comparing the statistics of the two operations, arrives at the following conclusions:

1. Intubation cannot completely take the place of tracheotomy; in cases in which one can choose between the two, the interests of the patient will usually demand tracheotomy.

2. The value of intubation cannot be determined from statistics. Each case should be studied with reference to its own characteristics and the localization of the disease.

3. The advantages of intubation are the ease and rapidity with which it can be done, the ability to dispense with anæsthesia and skilled assistants, absence of an external wound, and short duration of treatment. The disadvantages are necrosis from compression of the laryngeal mucous membrane, frequent entrance of food into the respiratory passage, frequent and painful attacks of cough, difficult expectoration of membranes and secretions, and deficient pulmonary ventilation, as compared with tracheotomy.

4. Tracheotomy should be preferred to intubation when the diphtheritic process is rapidly extending to the bronchi or involves them from the beginning, when the patients are very young and the muscles of expiration only slightly developed, when the disease has a septic character or has followed some other debilitating disease.

5. Intubation is indicated in cases in which the process is limited to the pharynx and larynx and does not show any septic characteristics.

6. If at the end of five days it is still improper to remove a tube which has been introduced, if alimentation becomes difficult and there is a probability that the disease has extended to the bronchi, the tube should be removed and tracheotomy should be performed.

THE MORPHOLOGY OF BREAST MILK AND THE NUTRITION OF THE CHILD.

An extensive study by Ivanoff (*Thèse de Saint Petersburg*, 1890) of this subject led him to the following conclusions:

1. The cellules of colostrum are of epithelial origin.

2. The multiparæ colostrum changes to milk more rapidly than in primiparæ.

3. Puerperal diseases retard the disappearance of the colostrum corpuscles.

4. These corpuscles reappear in the milk after ten months of lactation, and when the infant is only partly fed from the breast.

5. The free hyaline corpuscles, as well as those which are enclosed in the fatty globules, form a constituent of normal milk at a certain period of secretion.

6. Good health, good nutrition, and youth in the mother, give a milk richest

in fatty globules of large size, as is also true of the cellules.

7. The last portion of milk taken at a feeding holds fewer globules, and these of smaller size than the first portions.

8. The estimation of the nutritive quality of milk should be based upon the number of fatty globules; and, secondarily, upon their size, the quantity of cellular element, and, finally, upon the quantity of granules.

9. Milk which contains a very large number of fatty globules (more than 3½ per cent.) is not well borne by very young infants.

10. Milk, the globules of which are large, is less nutritive and less well borne.

11. The maximum of daily increase of weight of the child is produced by milk which contains a mean quantity of fatty globules of medium size (27.7 grammes daily).

12. The milk which contains few fatty globules gives little increase of weight (16 grammes daily); and the same is true if the fatty globules are in too great quantity or are too large (19 grammes daily).

13. Women who are thin and young in general are the poorest nurses, often making the children dyspeptic and giving them a mean daily increase of weight of only 11.5 grammes.

14. The microscopic examination of a freshly secreted milk give a sure indication of its nutritive value.

MEDICAL CHEMISTRY.

REAGENT FOR ACETONE.

Prof. Alf. Schwicker communicates a new method of detecting acetone to the *Chemiker Zeitung* (No. 52).

He found that a mixture of acetone and aqueous ammonia dissolves powdered iodine with evolution of heat. The liquid becomes turbid, and after a time separates iodoform. At the same time there is produced an irritating odor, causing tears in the eyes, which is probably due to iodine substitution compounds of acetone. No gas is given off, and the liquid is found to contain acetic acid.

This reaction may be used to detect acetone, for even traces of the latter dissolved in water respond to it. Moreover, *alcohol* does *not* produce iodoform under the same circumstances.

The best way to execute the test is as follows:

To the solution containing or supposed to contain acetone add a few drops of strong ammonia, and then 1 or 2 drops of a decinormal iodine solution.

This will cause a blackish cloud of iodide of nitrogen, which disappears on shaking or gently warming, and soon makes place to a yellowish cloud of iodoform if the liquid was not too diluted. By adding 1 or 2 drops more of the iodine solution, the amount of iodoform may be increased. After every new addition of iodine, and disappearance of the black cloud by shaking, a few moments are allowed to elapse. On shaking, the odor of iodoform will be distinguishable in spite of the ammonia.

In the case of a very dilute solution of acetone a more dilute iodine solution must be used.

Should the black iodide of nitrogen not disappear, but remain, it may be decomposed by the cautious addition of hyposulphite of sodium.

Solutions of acetone of 1 in 5000 yield a precipitate of iodoform after a few minutes, or at least exhibit a decided odor of iodoform.

Alcohol, as already stated, does not respond to this reaction, but aldehyde does. In this case iodoform is also produced, but the acid generated as a secondary product must in this case be formic acid.

SCOPOLAMINE.

Prof. Ernst Schmidt has recently given, at a meeting of German Naturalists and Physicians, some further particulars of an alkaloid separated by him from the root of Scopola atropoides some eighteen months ago, and provisionally named, scopolamine. The hydrobromide occurs in beautiful glassy crystals, and from the results of analyses of this salt and the hydrochloride, hydriodide, sulphate, and a highly characteristic gold salt, as well as of the free base, the composition of scopolamine is represented by the formula $C_{17}H_{21}NO_4$. Scopolamine appears to contain a hydroxyl group, as it yields a monoacetyl derivative; towards nitrous acid it behaves as a tertiary base. By boiling with baryta water it is split up into atropic acid and a crystalline base, melting at 110° C., which has a composition represented by the formula $C_9H_3O_2$. Professor Schmidt announced that the "hyoscinum hydrobromicum" at present met with in commerce consists essentially

of scopolamine hydrobromide. Scopolamine is said to have also been obtained in small quantity from belladonna root and from stramonium seed. The mydriatic basic substance separated by the author from one sample of Duboisia myoporoides consisted essentially of scopolamine, but that obtained from a sample of the leaves from another source was essentially hyoscyamine.

CLIPPINGS AND NEWS ITEMS.

CLASS BANQUET.

The "class of '78" of Jefferson Medical College held its fourth annual banquet at the Hotel Bellevue, December 29, 1891. The invited guests were Professors Da Costa and W. H. Pancoast, the two living professors of the faculty of 1878, and Dr. T. H. Andrews, with Dr. L. Webster Fox, class president, in the chair.

Among those present were Drs. Daniel E. Hughes, A. H. Hulshizer, Dr. Frantz, J. Moore Campbell, T. E. Conard, M. John Cummings, Nevin B. Shade, Lambert Ott, Harry Braus, H. Howard Drake, J. A. Wamsley, Dr. Arney, H. Page Haugh, Fred. A. Oliver, F. H. Carrier and J. W. Sampsel.

The next banquet will be held in Philadelphia, November 10, 1892.

AMERICAN PHARMACEUTICAL ASSOCIATION.

Membership in the American Pharmaceutical Association is obtained only by election at the annual meeting. "Every pharmacist and druggist of good moral and professional standing, whether in business on his own account, retired from business, or employed by another, and those teachers of pharmacy, chemistry, and botany who may be specially interested in pharmacy and Materia Medica," are eligible for membership. For blank applications and further information address, Dr. H. M. Whelpley, 2729 Washington Avenue, St. Louis, Mo., Chairman of Committee on Membership.

DR. LUCIA REDDING THOMPSON.

Dr. Thompson, one of our recent French correspondents, has returned to this city and will open a Sanitorium.

THE SONG OF THE SADDLE-BAGS.

BY H. C. S.

Faded and rusty, mud-spattered and worn,
Rifled of contents, bottles broken and gone,
Covered with dust, I hang here and mourn
For the days of yore;
When the world bowed down to me,
As I sang this song exultingly:—
"Now and forever, the whole round world wags,
To the rhythmic song of the saddle-bags!"

In palace and cottage, at sea or ashore,
'Mid sunshine or storm, I continued to pour
Forth my treasures of healing frail man to restore
To comfort and health.
Requiring no thanks, accepting no fee,
Again and again I sang joyously:—
"Now and forever, the whole round world wags,
To the rhythmic song of the saddle-bags!"

Like Napoleon I sigh'd, "the world is small!"
I longed for new races—to conquer them all.
I laughed when 'twas whispered I might have a fall
From my high estate.
I grew pompous and proud and vain as could be,
And continued my song exultingly:—
"Now and forever, the whole round world wags;
To the rhythmic song of the saddle-bags!"

Oh, 'tis bitter, indeed, that my hopeless disgrace
Shou'd be caused by a changeable human race
In its boasted progression (for such they've the face
To proclaim it!)
Old, battered, helpless, I accept the decree,
E'en though I murmur impatiently:—
"Never again! the whole round world wags,
To a *later* song than the saddle-bags!"

There's a lesson of sorrow for you in my song;
A lesson for all who believe themselves strong.
Remember that pride and great strength belong
To youth, and like me
The subject of jeers you may live to be,
As you childishly moan in your misery—
"Never again! the whole round world wags,
To a *later* song than the saddle-bags!"

—Indiana *Med. Journal.*

MEDICAL LEGISLATION IN OHIO.

Pursuant to call issued by the Cincinnati College of Medicine and Surgery for a delegated convention of the medical colleges of the State of Ohio, which was held at Columbus, December 3d, representatives of the following faculties were present, viz.: Starling Medical College, Toledo Medical College, Pulte Medical College, Columbus Medical College, Medical Department of the National Normal University, College of Physicians and Surgeons of Columbus, Woman's Medical College of Cincinnati and the Cincinnati College of Medicine and Surgery.

On motion, Dr. Starling Loving was elected Chairman and Dr. Charles A. L. Reed, Secretary.

On motion of Dr. C. E. Walton, representatives of the Physio-Medical Society of Ohio were admitted to a vote in the convention.

Dr. Charles A. L. Reed presented the following:

Resolved, By the Medical Colleges of Ohio, in convention assembled, that the Legislature be and is hereby requested to enact a law which shall embody the following features, viz.:

1. The creation of a board or boards of medical examiners in the composition of which equitable and just representation shall be accorded to the various recognized denominations of medical practice.

2. The examination of all candidates for the practice of medicine holding diplomas hereafter issued by medical colleges which shall be deemed in good standing by the board.

3. Exemptions from examinations to extend only to those who at the time of the enactment of this law shall be recognized as legal practitioners within the meaning of existing statutes; but all legal practitioners shall be required to register.

4. A penal clause which shall secure the enforcement of the foregoing provisions.

Dr. C. E. Walton, on behalf of the Legislative Committee of Cincinnati, presented the registration law approved and promulgated by that committee.

On motion by Dr. Shockey, the resolutions presented by Dr. Reed were approved.

On motion by Dr. Kinsman, the secretary was directed to forward transcripts of these proceedings to each local medical society in Ohio, and to the medical press.

On motion by Dr. Scoville, a committee was appointed to confer with the Legislative Committee of Cincinnati for the purpose of securing such changes in the bill proposed by that committee as to make it conform to the resolutions adopted by this convention.

The chair appointed as such committee, Drs. S. S. Scoville, T. C. Hoover, G. W. Mayhew and Chas. A. L. Reed.

Adjourned.

CHARLES A. L. REED, Sec.

STARLING LOVING, Chairman.

MORBID CHANGES IN JOINTS IN SYRINGOMYELIA.

The *St. Petersburger Medizinische Wochenschrift* publishes a *résumé* of Dr. N. A. Sokoloff's little work on the Morbid Changes in Joints observed in Syringomyelia. These changes occur, according to the author, very frequently. They are chiefly observed in the upper extremities, and are very chronic. A characteristic symptom of these affections, as in tabetic arthropathy, is their painlessness. It is easy to diagnose them anatomically and clinically. Fixation of the joints in the early stage of the complaint, or operative interference in advanced and marked cases, is indicated. —*Lancet.*

ARSENIC FOR TRICHINOSIS.

Dr. W. H. Merrill, Pepperill, Mass., in a very interesting article in the New York *Medical Journal*, reports a case of this very uncomfortable and usually fatal disease in which the administration of liq. potass. arsenitis in 5 drops three times a day, and increased 3 drops per day until the constitutional effects of the remedy became visible, effected promptly a permanent cure in about 25 days from the first dose. During the time as much as 36 drops were taken during the day, but as soon as arsenical symptoms were visible the dose was decreased temporarily. Although arsenic has not heretofore been noted as a remedial in this disease, yet the failure of nearly if not quite all other remedies in cases where the trichinæ were developed, and this case being so marked a success, warrant its trial in future and the publicity that can be given to this remedial.

SULFONAL IN TRISMUS NASCENTIUM.

J. Berenyi (*Pesther Medchir. Presse*) reports the case on an infant which on the fifth day after birth was attacked with trismic convulsions, having five crises in as many hours. These crises continued with greater or less frequency until the eighth day, resisting all treatment. Berenyi then administered sulfonal in 3-grain doses by rectal injection and by the mouth. The crises at once diminished in severity and frequency, and ceased completely on the sixth day, with no further return. The total amount of sulfonal administered was 150 grains, and at no time was there noted any tendency to somnolency or other untoward symptom due to the remedy.

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Sea-sickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:

℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF

RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form*.

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.

A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN

In Doses of from 10 to 20 Grains,

AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF

Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,

caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda.

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

CLINICAL LECTURE.

CHRONIC COLITIS—CHRONIC NEPHRITIS WITHOUT EXUDATION—CARDIAC HYPERTROPHY AND DILATATION WITH MITRAL STENOSIS AND INSUFFIENCY—SIMPLE ANÆMIA.*

By FRANCIS DELAFIELD, M. D.,
PROFESSOR OF PRACTICE OF MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

CHRONIC COLITIS.

Gentlemen: This man, 55 years of age, gives us the following history:

Over twenty years ago, in the army, he contracted a diarrhœa, which, despite treatment, has continued up to the present time. He continues to have from two to five small and watery passages a day, sometimes containing quantities of mucus, sometimes blood. During the last few years he has complained of pain and distress in the right side and back, swelling of the legs and a burning sensation in the feet and ankles. He is unable to work, and has not eaten solid food for the past nine months. He tells us he has been taking opium for the relief of his diarrhœa, but he had stopped this drug eight months ago. I questioned him closely, however, and he admits that he still takes a half drachm of laudanum two or three times a day. The examination of the urine, I am told, shows a sp. gr. of 1020 and no albumen.

Putting the man on the table, I examined his abdomen carefully by palpation and percussion, but fail to find any abnormality; nor would I expect to find any, for the history of this case is a straightforward one of chronic colitis. Whether there be ulceration or simply a chronic catarrh, I am unable to state, but it is certain that this catarrh of the lower part of the intestines has caused changes in the colon so profound by reason of its long duration that the colon cannot be restored to its normal condition.

In this patient before us, besides the colitis, there has been added the opium habit. Though we may believe what he tells us that the quantity of opium he is now taking is considerably less than formerly, yet the *habit* is undoubtedly established. With regard to the treatment of this case, I must confess that very little can be done. The indications are to relieve the diarrhœa and improve the man's general condition. It is idle to look for more. We shall put him upon small doses of castor oil—say 20 drops—together with tablespoonful doses of cod-liver oil twice a day. By this we hope to produce better fæcal passages, but do not expect to improve the condition of the bowel. This medication may be kept up indefinitely. His diet should be largely fluid, milk being the staple article. The question arises, should we try to make this man give up the use of opium? I do not believe it is worth while; he is old, and moreover, he looks like a man who has not long to live. The struggle to give up this habit would not only cause him great suffering but the success of our efforts would be very doubtful. I shall urge him, however, to decrease the dose he is now taking, or at least, promise not to increase it. You hear, he volunteers the statement that he will give up the opium altogether, but of this I am very doubtful.

CHRONIC NEPHRITIS.

This woman is fifty years of age; she has the appearance of having been accustomed to hard work and privation. She has come to the Clinic complaining of

* Delivered at the Vanderbilt Clinic of the College of Physicians and Surgeons.

fainting spells, which she tells us, she has been subject to for about eighteen years. They are produced by worry and excitement and fatigue. At first they recurred about once a week, but lately they have been more severe and further apart. They would come on with a feeling of faintness and trembling all over the body, but without pain or nausea or complete loss of consciousness, sometimes with palpitation of the heart and sometimes without. They would last an hour or two, or perhaps an entire day. During the past year her feet have occasionally become slightly swollen. Her urine has been examined; the sp. gr. is 1005, and it contains a trace of albumen. The radial pulse, I find, is very feeble at both wrists; it numbers 88 to the minute. The heart's action, by auscultation, I discover, is also feeble, but there is no murmur, nor does the heart seem altered in size.

This, therefore, is a case of chronic nephritis without exudation, and though it must have existed for some time, judging by the low sp. gr. of the urine, and produced marked changes in the structure of the kidney, yet it has caused no symptoms except this slight dropsy that has appeared lately. It is an example of that class of renal disease wherein there is nothing much to demand treatment.

This woman has worked hard; has probably been often without sufficient nourishment and has probably used alcoholics. Could we change her condition of living, we would benefit her, no doubt. But this we cannot expect to do. As for the attacks of faintness, they are almost certainly not due to organic disease, but are such attacks as any nervous woman is liable to as the result of worry and over-work. The feeble action of the heart is the only symptom that, at the present time, might demand treatment. This would suggest the propriety of trying a cardiac stimulant. It is doubtful, however, how much benefit would be produced. I should order this woman the fluid extract of digitalis, two minims three times a day. Let her take this for one week, and if she does not improve, I should be inclined to give her no medication for the present; that is, it would not be well to tell her she was receiving no treatment, but give her a placebo and keep her under observation.

CARDIAC HYPERTROPHY, ETC.

I now show you a man, 42 years of age, who says that, with the exception of having had rheumatism off and on for the last thirty years, he has been in good health up to three or four weeks ago. Since this time he has complained of some shortness of breath and oppression over the heart on stooping or on working hard. He has complained also of palpitation at times, though he has been able to work at his trade of street paving up to to-day. His urine is said to have a sp. gr. of 1023 and to contain no albumen. He has been under treatment at the Clinic here, and has been taking iodide of potash and nitro-glycerine. As I take his pulse I note it is soft (which may be due to the drugs he is taking) and also that the artery is somewhat tortuous and the walls hard and resisting. The arterial tension is not increased therefore, but the vessel is the seat of chronic endarteritis. Inspection of the chest shows the apex beat displaced to the left, well circumscribed. By auscultation the heart's action is found to be irregular and intermittent, and not very strong nor yet very feeble. I hear distinctly a systolic and also a presystolic mitral murmur, not transmitted posteriorly.

This man's condition, then, is a serious one. He has endarteritis that has probably existed for a long time, and mitral stenosis and insufficiency, together with considerable hypertrophy and dilatation of the left ventricle. How can we account for the fact that, with this state of things, the patient has been able to continue at hard work and free from symptoms until within the past month? I think the explanation is to be found in this—that his kidneys have remained in good condition. This is evidenced by the examination of the urine. Should this man be sent to bed or confined to the house and put upon fluid diet, as you have frequently heard me advise in cases of irregular and weak heart with arterial disease? I do not think it necessary. On the contrary, I believe he will be better for a generous diet and moderate work and exercise in the open air. In the mean while we will try to put the heart and pulse in better condition. We should bear in mind that in these cases the condition of the circulation is different at different times; the arteries are sometimes contracted, at other times not. Hence it will be necessary to change the

remedies according as this or that indication arises. Two weeks ago we presume there existed a high arterial tension, since nitro-glycerine was given. Now this condition is not present. The irregularity and the intermittent action of the heart are the pronounced symptoms to-day, and for these the fluid extract of digitalis, m. ij., t. i. d., should be employed. And if it be certain that two weeks ago there was a condition of contracted arteries, potassium iodide, gr. v., should be added to the digitalis. I use Squibb's fluid extract of digitalis now altogether in cases of heart disease, in preference to the tincture and infusion. Its action is more certain and reliable; even a fraction of a minim will often produce the desired effect, and two minims may be considered a good dose. This patient may continue fairly comfortable doing his work, and free from dyspnœa and palpitation for the greater part of the time for some years, notwithstanding the serious disorder of his heart.

ANÆMIA.

This young girl, 21 years old, comes before us with the following symptoms: For the past three years, she says, she has suffered from attacks of shortness of breath, pain about the heart, nausea and vomiting and œdema of the feet. Under treatment these symptoms would subside but to return again, and in this way they have subsided and recurred several times during these three years. Her pulse, I find, is 120, but not feeble, and the artery is not changed nor the tension abnormal. Indeed, such a pulse would not direct attention to the heart. The examination of the heart is also negative; its action is regular. The urine does not contain albumen and its sp. gr. is 1022. Investigation shows, therefore, that the heart, kidneys and liver are not at fault, but attention should be directed to the blood. This should be examined; the amount of hæmoglobin and the number of corpuscles estimated. This would probably settle the question of diagnosis. There seems to be no doubt from the history, however, that the patient is suffering from the simple anæmia of young women. Such cases are apt to improve and then grow worse, and so fluctuate between good and bad health for a long time. The treatment, of course, is iron, but it must be persevered in. It is necessary, in fact, to administer it the greater part of a year or two, or until we are satisfied that the disposition to relapse has been removed.

PTERYGIUM.

By P. D. KEYSER, M. D.,

PROFESSOR OF OPHTHALMOLOGY AT THE MEDICO-CHIRURGICAL COLLEGE, OF PHILADELPHIA.

Gentlemen:—Pterygium is a growth of the bulbar conjunctiva of a triangular shape, with its apex pointing towards the cornea, and when trangressing on the cornea in its progress towards the centre, invades only that side of the cornea from which it comes. It is peculiar in that it very rarely, if ever, passes over the centre of the cornea; when it reaches that point its advancement seems to stop, but it is apt to spread out on the sides, becoming wider and thicker. Its shape, position and manner of growth are of diagnostic value.

The growth in the conjunctiva may be thicker or thinner, or broader or narrower, according to how it forms in the tissue. It is really a hypertrophic condition of the conjunctiva, containing vessels of various calibre and number. At times, strictly speaking, it is solely in the conjunctiva, which can be readily moved or raised over the sclerotica; at other times, especially when thick rigid and tendinous, it may be somewhat attached to the underlying capsule of the sclerotica. When on the cornea, it is thick, rigid, tendinous and firm, like connective tissue in neoplastic formations.

It is formed generally on the inner side of the ball, at times on the outer, sometimes on the inner and outer sides together, growing towards each other, and very rarely on the direct upper or lower surfaces. Its growth, however, is in the conjunctiva, over the line of the recti muscles—very few cases have been reported lying between the recti muscles. It generally starts from the inner canthus as a lot of small vessels, with one or two longer ones, extending beyond the others towards the corneal region. With these vessels, a certain amount of thickening of the tissue takes place, which spreads out fan-like, and slowly enlarges and thickens, creeping towards the edge of the cornea. When up to the cornea at the limbus conjunctivalis, it seems often

to be arrested in its long or meridional axis, and for years may not encroach on the cornea, but all the time becoming thicker and broader in the conjunctiva. At times it may be inflamed, and at others perfectly quiet and cause no trouble or ill feeling in the eye. As long as it remains in the conjunctiva the vision is not in the least affected by it. But after some time, which may be years, it begins to develop in or across the cornea; as it does so it assumes a tendinous or whitish appearance, resembling often a thick scar. When it begins to creep across the cornea, it may be noticed that there is a line of opacity spreading a considerable distance in the corneal tissue ahead of the pterygium itself, showing a certain amount of inflammatory action and filling in of the clear nutrient canals of the cornea. Two forms of pterygium have been distinguished—the true and the false—which differ only in a few particulars as to peculiarities of shape, thickness, etc., but are the same in character as to generalities and treatment, and therefore I describe to you to-day, with these cases, the general form and appearance, so that you can diagnose such cases and attend to them properly.

It has long been a mooted question as to what is the cause of this affection. It is a well known fact that it is an inflammatory process, but of a very subacute or chronic form, causing very little, if any, inconvenience for a long time. Some claim it is the result of small ulcers of herpetic character, which may occur in the conjunctiva and in the cornea, the healing and shrinking of these ulcers drawing the conjunctiva towards them. Others again do not agree in this view. The idea has also been given that this affection depends on venous thrombosis, or narrowing of a corneal and of a vena vorticosa, thus developing disturbances of circulation in the corneal portion of the ciliary arteries penetrating the recti muscles. In later years it has been claimed to originate from micrococci which becomes deposited in the conjunctiva and creeps along over on the cornea with a certain amount of inflammatory process following its track.

Whatever may be its cause, we well know its appearance, and when once developed and formed, to a certain degree it is permanent, and can only be removed by operative interference. It is found mostly in advanced life and very seldom in young people, while there are certain occupations in which persons appear to be prone to it.. It is seen very frequently among seamen, even in comparatively young men. A former student of mine, Dr. Chandler, of the Island of Barbadoes, informed me that a great many of the colored people on that island were affected with it.

Some years ago, I took up the study of inflammatory diseases arising from strain, from defects in refraction of the eye, and in all cases of pterygium, whether in the conjunctiva alone, or on the cornea, I found some marked degree of compound hypermetropic astigmatism.

A curious feature in connection with pterygium, is that it will creep across to the centre or apex of the cornea and there stop. I may almost say that it has never been known to grow completely across the cornea from one side to the other; we may, however, have another like growth starting from the opposite side, either at the same time or later, which will grow until its apex almost reaches the centre of the cornea, but never quite meeting its fellow of the opposite side.

In looking over the field, we may correctly say that we really know nothing positive as to its cause, except that it commences as a small ulcer, with the small vessels of the conjunctiva running towards it, which gradually thickening grows toward the cornea, on the edge of which it sometimes remains for five, ten, fifteen or twenty years, and all at once again begins to grow and spread across the cornea. When this occurs, there is only one remedy, and that is operation as quickly as possible. If it grows over to the centre of the pupil, no matter what method is used in its removal, it leaves a cicatricial opaque condition of the cornea, leaving it just like ground glass, so that the patient is disappointed when he does not see perfectly after the operation. Therefore, always advise the removal of this growth as soon as it begins to spread over the cornea. It is not wise, however, to operate before this time, as it may take many years before such a growth will commence to invade the cornea, and it does no harm until it starts that stage in its development.

One thing I want you to remember is, that this condition is not cataract. The common idea among the people, and, I regret to say, among some physicians, is that cataract is something which grows

over or on the eye. I have had physicians send cases of pterygium to me under the name of cataract. Cataract is an opacity of the lens and occurs naturally in the eye-ball, while pterygium is an external growth.

Many methods have been proposed for the removal of pterygium. The first was to grasp the growth with a pair of forceps and cut it off with the scissors, leaving a triangular opening in the bulbar conjunctiva to fill with granulations. Where the growth was large on the cornea, it was shaved off with a knife and then the scissors used to remove the conjunctival part. But in this operation, it was often found that a return of the growth occurred, which was more difficult to remove on account of a firm attachment to the sclerotica. To remove this secondary danger, an improvement was made in not cutting the triangular piece out of the conjunctiva, but cutting back along the margin on either side of the growth, and allowing it to fall down and recede by gradual absorption, while the conjunctiva is brought together over the wound, covering up the space from which the growth has been removed. Then again, instead of letting the excised part fall down for a long, slow absorption, a good improvement was throwing a ligature around it and so causing it to slough off in a few days, while the triangular space, being covered by drawing the conjunctiva over it, heals up. Ligation has been tried. Szokalski suggested a very ingenious method of passing ligatures around the growth and causing it to slough off. This method, however, is seldom used.

Transplantation has been made with success, especially in very large and broad growths. This is done to relieve or prevent the retraction of the conjunctiva, which is liable to take place where a great amount of that tissue is removed and interferes very much in the mobility of the eye-ball. In this operation, the growth is turned up into an incision in the conjunctiva on the upper part of the ball. But if the pterygium is very broad it is much better to split it down the middle after its separation from the cornea and conjunctiva, and transplant one half upward and the other half downward.

A very easy and simple, as well as successful, method, has been lately introduced for the removal of this growth from the cornea when its attachment is not too deep in the corneal tissue. Generally, the attachment of the pterygium in its growth over the cornea, is superficial and only to the anterior layer, from which it can readily be torn, so, by forceps or a strabismus hook under it, it can be pulled away from the cornea. The apex recedes and the conjunctiva is brought together on the line contiguous to the cornea.

Now, gentlemen, I have two well-defined and very different cases of this disease to present to you to-day. The one I first show you has been growing for years; you see the patient is an old man. The growth extends almost to the centre of the pupil and spreads out in the conjunctiva, fan-shaped, towards the inner canthus, so broad as to cover almost that side of the ball. It is too large to dissect up and remove, so I shall divide it and transplant one half above and the other half below. I first take up the thick tissue in my forceps, and with the scissors make a small opening along the upper border of the same, near the cornea, and one on the lower edge immediately below it. Through this I pass a strabismus hook so as to lift it up, drawing from the cornea, at the same time grasping the corneal part with my fixation forceps to aid in pulling the growth off the cornea. Now, having done so, I cut on either side back to the ball, and dissect it up loose, and then make with my scissors a curved incision in the conjunctiva above the cornea on the top of the ball and an incision in the lower part. I now split the pterygium straight down its centre to the base and then turn each half into its new position in the conjunctiva and fasten by sutures. The second case I show you is of much smaller growth, and not spread out much in the conjunctiva. In this case I shall only draw or tear the corneal attachment loose in the same way as I did the former operation, in and let the apex of the pterygium recede back from the cornea, and then draw the conjunctival wound together to cover the gap made. The thickened part, or apex, gradually shrinks away, so that in a short time very little, if anything, remains to be seen.

This tearing the growth from its corneal attachment appears to have many advantages, and is a great improvement on its removal by cutting. When cut or shaved off, considerable opacity remains, and often a thickened, firm, tissue-like prominence.

The attachment seems to be rather superficial, not passing into the deeper tissues of the cornea, but fastened by little filaments which take only slight hold upon the anterior layer, so that simply by pulling it gently, the attachments are broken loose, and a more or less clear cornea remains.

COMMUNICATIONS.

THE ORGANS OF HEARING AND LIFE INSURANCE.

(Translated from the works of Dr. Josef Gruber)

By LAWRENCE TURNBULL, M.D., P.H.G.,
PHILADELPHIA,
and
S. W. STEINBACH. M.D.,
PHILADELPHIA.

The examination of a candidate for admission in a life insurance company by the aural physician should solve the three following questions:

First.—Is the life of the individual in question endangered by the condition of his organs of hearing; if so, to what degree?

Second.—Has the ear affection any connection with other local or general affection; if so, what is the connection?

Third.—What is the relation of the special disturbed function of the ear, more especially with reference to the following of the vocation, or would it invalidate the policies or militate against the individual to be insured?

Everyone who is even partially initiated will be able to perceive by these questions alone what knowledge is required for their proper solution, and how, in doubtful cases, a recourse must be had to the judgment of the more experienced. Even the judging of the average case will be made more easy to the less experienced physician if the points for the formation of a diagnosis are indicated to him.

The statements of the patient, as elicited by oral examination, will be of the greatest interest, but we must be guarded, so as not to be too credulous, and try always to ascertain, by an objective examination, whether the patient's statements can be made to harmonize with the existing condition of the organs of hearing.

It is not intended here to say that the statements of the individual must, in every case, be confirmed by a positive or negative result of an examination, for the objective examination generally gives a negative result in those cases where the functional disturbances may be the most detrimental to the individual's capability; *e. g.*, in those produced by a primary or secondary labyrinthine lesion, where the objective examination gives frequently a completely negative result. It is the case of those individuals who desire to be admitted into a life insurance company that they attempt to conceal their aural affections, which occasionally are very dangerous, or they try to at least underrate the significance of their ear diseases and then the objective result (of the objective examination) must correspond with the respective statements. We are in favor of allowing the individual about to be examined to relate his own history of the affection, and then complete and purify his statements by appropriate questions. Very often the physician's attention will thus be led to points which he otherwise would have overlooked.

The objective examination of the organs of hearing may be divided into an ocular, tactile and auscultatory, and should be conducted with the greatest exactness, more especially as regards the relation which it bears to the organism at large. In my hand-book, published by C. Gerold's Son, in Vienna, the various methods of examination are carefully detailed. The limited space here does not admit of a more thorough consideration of the subject, and I, therefore, must refer to that work, and proceed to at once, commencing in anatomical order from without inwards, mentioning and elucidating those symptoms which are of the greatest importance to the diagnosis in the prognosis of diseases of the ear.

A. External Auditory Portion.—First we consider the neighborhood of the pinna. Inflammatory swellings of the soft part, irritative swellings of the lymphatics, especially those in the maxillamastoid fossa, and at the mastoid process, fistulous pus-tracts in this region, as well as swelling of the mastoid process, especially when all these appearances last long, they are frequently to be regarded as the consequences of serious affections of deeper structures, dangerous to the life of the individual.

Great attention must be paid to ulcerated surfaces in this region and those on the pinna, for they are occasionally the expression of a carcinomatous degeneration, only to be diagnosed by the use of the microscope. Fistulous tracts should be explored carefully, which may lead to a detection of the condition of the bone and of the original seat of the affection. Occasionally in the swelling of the lymphatics in the mastoid region is connected with affections of the ear, which is only a part appearance of a general lesion, namely syphilis and scrofulosis. I must here emphasize that I have often seen cases where the appearances in and about this region were the first signs of a constitutional syphilitic affection that had made itself manifest. Ulcers of the pinna itself are occasionally the result of constitutional syphilis, or they may be of a lupus or carcinomatous nature. In a far progressed gouty affection, deposits are not infrequently found in the pinna. Hæmatomes occur here as neoplasts of a local importance, only the so-called othæmatom might in one case or another be connected with other affections of the vascular system. Foreign masses in the external auditory canal, including the accretions of cerumen, must first be removed in an appropriate manner, so as to gain an accurate insight into the deeper sections. Here it may be mentioned that occasionally cholesteatomes proceed from the deeper sections of the same into the auditory canal, where the newly formed mass easily mixes with cerumen, assumes its color, and may give rise to great errors.

Inflammatory affections of the external auditory canal are to be judged with reference to the functional data and general appearances. When such exudative processes are connected with great swelling of long standing of the soft structures, and especially when connected with increase in size of the bony portions, when polypi appear in the auditory canal, when probably pieces of bone have escaped, they always awaken a suspicion of caries or necrosis. I wish particularly to emphasize that only very rarely can a diagnosis with the ordinary surgical methods of examination be obtained in an affection of bone located in the deeper seated portions of the temporal bone, because the probe, in most cases, does not reach the affected portion at all. The diagnosis must be made with the aid of the microscope, periodically examining the masses removed from the auditory canal.

In bone implication, small particles will be found which will furnish the surest proof of the presence of caries or necrosis, especially if the examination has been conducted with appropriate care. When polypoid growths are present in the auditory canal, a microscopical examination will furnish a solution of their specific character; some, although rare, appear as carcinomatous neoplasms.

The appearances on the membrana tympani call for the most thorough consideration, because from it we can diagnose not only those affections that have their seat in the membrane itself, but frequently we can, from it, judge the condition of neighboring organs, especially the bearing of the scructures of the middle ear. Opacities of the membrane are most frequently connected with diseases of the structure of the middle ear, especially when they present an arched (semi-circular or circular) appearance; these affections may, in a great degree, endanger the power of hearing. Polypoid growths on the membrane and perforations with contemporaneous continuous or periodical otorrhœa go frequently hand in hand with dangerous inflammatory diseases, and merit the greatest attention. Perforations of the membrana tympani become free from danger to the deeper structures generally only when the otorrhœa has long ceased and the mucous membrane has become sclerosed.

B. Middle portion.—In this portion of the ear we find mostly those diseases localized which, on one hand, may become dangerous to the life of the individual, and, on the other, cause difficulties in hearing, or other unpleasant consequences. To expose the condition of this portion of the organ of hearing, the physician must direct his attention to all those parts which stand in any relation with it: the auditory canal and the membrana tympani, and also the structures in the neighborhood of the mastoid process, the nasal and pharyngeal regions; for not infrequently important and substantial affections of the middle ear spread their noxious influences hither, or are occasionally even the result of primary affections of these structures. In judging of the results obtained by the various methods of examination, the general condition must be considered,

and we must not precipitatedly make a diagnosis, because the most experienced is often enabled to make a proper diagnosis only after repeated and protracted examinations. This is more particularly the case with reference to the so-called dangerous caries or necroses, which are often seated so hidden that they do not betray themselves to the most experienced eye. The microscopical examination of the discharge from the ear, or a fistule, as mentioned before, will soonest and best furnish an explanation. Since the long-existing and profuse otorrhœa is no sure sign of caries, so we, on the contrary, must not conclude the opposite to be the case from a temporary or complete cessation of the same, and the physician must build up his diagnosis and form a prognosis from all the appearances within and without the organ of hearing.

Let it be mentioned here once more that the nasal and pharyngeal examinations must be conducted with the greatest minuteness, for occasionally there occurs in the middle ear only the simplest signs of an inflammatory process, while in the nose and pharynx syphilitic and carcinomatous degenerations are carrying on their destruction.

C. Internal Ear.—Life is seldom, if ever, endangered by primary affections of the labyrinth. The connections of the internal ear serve frequently as conductors of dangerous diseases from the middle ear to the brain or its membranes, and thereby cause a fatal termination. . On the other hand, it is evident that diseases of the brain of a dangerous character extend to the auditory nerves and the labyrinth, and from this point betray their existence, and, like general lesions, assert their noxious influence upon the organ of hearing.

Concerning the capability of the individual to self-support, or of the expected or already existing invalidity of an individual, we will have to consider, not alone the existing forms of ear disease, the degrees of disturbances of hearing, and other subjective symptoms, but also the occupation of the patient.

A rationally managed insurance company will allow this rule to stand at the acceptance as well as in the act of declaring a policy invalid.

CASES AND CONCLUSIONS.

By LAWRENCE TURNBULL, M. D.

The great importance of a critical examination of the organ of hearing before a policy of insurance is issued to an individual suffering from ear disease, is well shown in the preliminary article by Professor Gruber, of Vienna, translated by my friend and pupil, L. W. Steinbach, M. D. Cases are frequently presented for our examination in which, to all appearance, the individual is in perfect health, yet there is a slight discharge from one or both ears. We cite a case in point. A gentleman, W. H., aged forty-two, presented himself for our examination, and he made very light of a discharge from the ear, which he stated had existed for years and only required cleansing once a day, and gave him no trouble. We told him of the great risk he ran of a sudden cold being taken during imprudent exposure which might cause his death. He was not considered a good risk. There was a perforation of the drum membrane and discharge. His family history was good. His father had lived to a good old age. This discharge, in connection with the grippe, was ultimately the cause of this young man being cut off before he reached the age of 45 years, the normal period of longevity. This suppuration from his ear of so long a continuance had destroyed the lining membrane which covers the delicate bone of the part and this was followed by ulceration and necrosis of the bone forming the roof of the middle ear (tympanum), and the next scene was abscess of the brain and death. Another form of ear disease which would prevent the issuing of a policy as a first-class risk, is in cases where there is disease of the bone, the temporal especially being invaded, propagation along the Fallopian canal; involvement of the facial portion of the seventh pair of nerves, causing what is termed facial paralysis. We have met with several cases of this form of disease of the ear, and three of them recently. The first arose from an acute attack of chronic catarrh of the tympanic cavity, which had existed for years with the entire loss of hearing for one ear, and caused another chronic tympanal disease, with very imperfect hearing, in the other. Fortunately local depletion and aconite relieved the prominent symptoms

of fever, etc., in the first instance, and in the other with very large doses of iodide of potassium, even up to 100 grains a day, recovery occurred entirely in a month's time. The second was the result of a chronic discharge from the ear with loss of the drum membrane followed by extensive disease of the bone, which had been treated three years before with success by scraping, and the patient had been free from discharge and pain for three years. The disease again showed itself by a bloody discharge with severe facial paralysis, loss of power over the face, and falling of the eyelid, so that the latter had to be supported for months with a strip of isinglass plaster. A prolonged treatment by cleansing, antiseptic washes and the internal adminstration of the iodide of potassium, and then the "four chlorides" have almost restored the function of the nerve and the power of the eyelid and face, but it is liable to relapse. The third case was a patient in Jefferson College Hospital. The condition of the ear and face was the direct result of the poison of secondary syphilis, and was cured by a long continued course of mercury.

Another large class of cases which cannot be accepted as first-class risks, are those where we have diseases of the mastoid cells (just back of the ear) and forming the air cells of the middle ear. Numerous cases of sudden death follow the neglect by the surgeon to remove the diseased bone.

The last class of cases are those apparently of slight ear disease in which we have a thin watery discharge during the early state of tuberculosis, but which is followed and kept up by the increase of the cough, and in which no local or general medication is of any avail. Persons with a persistent cough, dullness at the apex of the lung, and a discharge from the ear we consider far from being a good risk for life insurance. Simply defective hearing, so that the individual cannot hear the human voice loudly spoken within a few feet, is apt to lead to accidental death in crowded streets or at a railroad crossing. Some insurance companies, both in this country, in England and on the continent of Europe, refuse under any conditions to accept any one suffering from an otorrhœa. We fully agree with our revered friend, the late Dr. Cassells, in that this rule of procedure is too sweeping, for there are many cases of ear disease with tissue lesion only in which there are reasonable grounds for saying that, inasmuch as the ear discharge is simply an excessive secretion from hypertrophied tissue, or at all events not the results of an ulcerative process either of these or the underlying bone, there may be a healthy constitution with no tuberculous, syphilitic, scrofulous or other history.

Under proper treatment many cases can be permanently cured and all discharge arrested; therefore, such cases should be accepted. In severe cases there might be an additional increase of premium. All suspected and questionable cases should in every instance be submitted to the critical examination of an expert in otology.

1502 Walnut St.

OPHTHALMIA NEONATORUM AS A CAUSE OF BLINDNESS.*

By T. B. SCHNEIDEMAN, M. D.,
PHILADELPHIA.

My object in bringing this subject before the Society is to direct attention to a disease which is responsible for about one-third of all cases of blindness, of which a most important means of prevention—that of public legislation—can only be obtained by the active intervention of medical societies. The following case is presented, not because of its novelty, unfortunately, but as somewhat typically representing the lamentable result of negligence or ignorance:

H. M., age three. Both eyes became sore when five days old. O. D.: Dense adherent leucoma lower inner portion of cornea. Remainder of cornea hazy, stretched blue-gray iris in contact with it. Globe apparently somewhat distended; leucoma prominent but easily covered by lids. T.: Normal. O. S.: Leucoma slightly denser and more prominent but not larger. Broader space of translucent cornea than O. D. R. and L. light perception.

The subject has been very thoroughly worked out in Europe, and a mass of statistics has been accumulated. According to the report of the Royal Commission on the Blind, published in 1889, 30

* Read before the Philadelphia County Medical Society, December 9, 1891.

per cent. of the inmates of the institutions, and 7000 persons in the United Kingdom, have lost their sight from this cause. Professor Magnus, of Breslau, finds that no less than 72 per cent. of all who become blind during the first year of life are rendered so by purulent ophthalmia; and even of those who become blind before the twentieth year of life, it constitutes as much as 23.50 per cent. Looking at the subject in another way, he shows that of 10,000 children under five years of age, 4.28 are blinded by purulent ophthalmia. In the blind asylums of Switzerland the proportion who have lost their sight from this disease is 26 per cent.; in the asylums of Austria, Hungary, and Italy, about 20 per cent.; while in Spain and Belgium it falls to about 11 or 12 per cent. And in this city, Dr. Harlan, as the result of examination of the eyes of 167 inmates of the Pennsylvania Institution for the Blind, found that 55 owed their affliction to purulent ophthalmia, and more than half of these were of the form occurring in infants.

The lesson taught by such statistics is not simply that ophthalmia of the newborn is the most common cause of blindness; if that were all, they would, no doubt, still preserve a melancholy interest, but they have a much greater importance, for they tell us that it is quite within our power to have prevented the great affliction of blindness in one-third of those who are deprived of sight. For it is hardly too much to say that no one should lose his sight from this disease, not only because it is quite amenable to treatment, if this be instituted from the beginning, but because the disease itself can be prevented in most instances if those who have the care of mother and child understand the nature of this affection.

Ophthalmia of the newborn is an *infectious* disease, and can only occur after the infectious matter has come into actual and somewhat prolonged contact with the conjunctiva. The noxious matter is in every instance derived from an inflamed vagina (or urethra), or from another eye. In the great majority of cases infection takes place from the vagina, and it is to be remembered that the disease is not caused by the secretion of a specific (gonorrhœal) catarrh only, but that it may be produced by the secretion of a simple leucorrhœa, or at least by what is recognized as such clinically.

As regards the period when infection occurs, this may take place either during or immediately after birth, or at some subsequent moment. In the former case, the *materies morbi* is derived directly from the vaginal secretion. The child passes through the parturient canal with closed eyes, hence during the passage of the head the secretion can only penetrate into the conjunctival sac in very small amounts, if at all, but it remains adherent to the eyelashes and edges of the lids, and can readily gain an entrance into the eyes as soon as these are opened and the child winks upon the escape of the head. Infection may take place during birth, if anything occurs to displace the soft parts of the face, as may happen in protracted and difficult labors, large size of head, etc., conditions more likely to be present in primiparæ, and with the larger heads of male children. But the time most fraught with danger is usually the moment the head escapes and the child first opens its eyes. In the majority of cases, infection takes place at some time during labor, and the disease first manifests itself from the second to the fifth day; if it does not appear until later, infection took place subsequent to birth. This may happen by the transference of secretion to the child's eyes in various ways, as by the hands of the attendant, by soiled linen or sponges, etc.; but the lochial discharge, as such, has been found to be incapable of causing the affection, if the woman be free from disease.

The discovery of the gonococcus has led investigators to examine the secretion of purulent ophthalmia for the same organism—and in the vast majority of cases examined it has been found to be present therein also; still, different observers appear to have reached results not entirely in accordance as to the relative frequency with which this organism is present. Cases do occur in which it cannot be found. Hence the attempt has been made from a bacteriological point of view to recognize different forms of the disease—a specific form and simple inflammatory forms. As stated above, the secretion of simple vaginal catarrhs are capable of causing purulent ophthalmia.

Formerly this disease was attributed to a variety of causes, such as injuries received by the eyes during birth, icterus, chilling of the body, intense light, etc.,

but these views are, of course, no longer entertained. Ordinary pus and even decomposed pus cannot produce it. Purulent secretions from lachrymal abscess and caries of the orbit frequently get into the eye, and do produce inflammation of the conjunctiva, but not the ophthalmia of the newborn with its great liability to involvement of the cornea. Putrid flesh, putrid blood, and even pure cultivations of various microörganisms, have been introduced into the conjunctival sac without any ill effect.

Prophylaxis, to be efficient, must, of course, first of all recognize the infectious nature of this affection, and secondly, the source whence the infectious matter may be derived.

Among general measures are to be placed all influences which can be employed to impress upon the public the dangerous character of all affections of the eyes of young children. Like all similar diseases, this affection is most prevalent and destructive among the poorer classes, who do not usually employ a physician to attend them in confinement, but rely upon a midwife too often but little better instructed than the woman she attends.

In some dispensaries for the treatment of diseases of children, a small tract is handed the mother or attendant who brings the child, giving advice as to the proper care of infants, their diet, bathing, etc. A few lines might be added, calling attention to the serious nature of this inflammation—ignorance of which and the proneness to ascribe every affection to "catching cold," which will get well of itself, is responsible for many ruined eyes. With this end in view, it might be advisable to have articles appear in the public prints from time to time explaining the danger of the disease in question, and urging the importance of immediately attending to every case of inflammation of the eyes of the young child. Even the ignorant classes understand the dangerous nature of certain other diseases, such, for example, as diphtheria and scarlet fever, and if ophthalmia of the newborn could be added to these, the deplorable results of neglected cases would be less frequently observed.

To reach this class (which is undoubtedly responsible for the great majority of those unfortunates who have become blind from this disease, namely, midwives), it has been proposed to compel all such to report every case of ocular inflammation at the earliest possible moment to some physician. Such laws are in force in certain countries of Europe, and there appears no good reason why a similar law might not be enforced in this country, just as there are laws requiring other contagious diseases to be reported. If this could be done with any degree of efficiency, it would do more toward abolishing loss of sight from this cause than any other measure. The State of New York has such an act in operation, requiring midwives and nurses to report every case of inflamed or reddened eyes occurring within two weeks after birth to some legally qualified practitioner within six hours, under penalty of a fine or imprisonment, or both. This law has been in operation for a little more than a year, and it is hence too early to obtain much information as to its practical working. A few convictions would direct the attention of that class which it is desired to reach to this subject, and in this way, at least, be productive of a certain amount of good.

As regards special measures of prophylaxis, these were clearly formulated as early as 1807 by Gibson, in the following ing principles, which all later experience has tended to confirm. They are, first, to cure the leucorrhœa of every pregnant woman when possible; or failing in this, second, to disinfect the vagina during labor; and third, to remove the secretion from the child's eyes immediately after birth by a fluid which renders the secretion harmless.

Notwithstanding their importance, I shall here pass over the first two and consider briefly the third of these indications. Of all the methods employed, none have yielded better results than the one recommended by Credé. This consists in dropping into the eye a two per cent. solution of nitrate of silver after simple preliminary washing with clean water. Other agents, such as carbolic acid and boracic acid, have been tried, but none gave results so satisfactory as the silver, perhaps because the latter has the power of penetrating deeper into the tissues. As a proof of the efficacy of this procedure in diminishing the number of cases of purulent ophthalmia of the new-born, the following figures, all obtained from the same hospital and the same attendants, furnish the evidence :

Children.	Treatment.	Per ct. of blenorr.	Per ct. of catarrh.	Total.
1092	No treatment . .	4.75	14.5	19.25
1541	2 per ct. of carbolic acid	1.42	.6	7.42
1250	2 per ct. of silver nitrate	0.72	4.72	5.44

And similar good results have been obtained in other lying-in hospitals. Still, this method, which is somewhat severe, is not necessary in every case in private practice, although, even if unnecessary, it is quite devoid of serious danger. As a milder measure, simple washing the eyes with clean water as soon as the child is born has been found efficient in diminishing the number of cases of the disease —while in any case in which there is a history of copious purulent discharge from the vagina, it would be advisable to employ the silver solution as recommended by Credé.

As regards the disease itself, it is almost superfluous to present any formal description; its phenomena are so characteristic that it is impossible to mistake its nature when fully developed. The swollen and reddened eyelids, the upper drooping and partially overlying the lower, the great difficulty or even impossibility of opening the eyes, the profuse purulent discharge welling forth as the lids are gently separated by the finger, the pain and heat, the swollen conjunctiva, rising like a mound, in which the cornea is buried, all these go to make up a picture which cannot be overlooked nor confounded with any other. But that every inflammation, however slight, affecting the eyes of a new-born child may, if neglected, become the fully developed disease, and that, too, in a day or two, should always be in the mind of every one who has any connection with the case.

The danger of this disease consists, of course, in the great liability of implication of the cornea, leading to perforation of this structure, with the serious results dependent thereon. It was formerly believed that the cornea, being an avascular structure, became affected from interference with its nutrition by the pressure of the swollen conjunctiva, but while such pressure may be unfavorable to the nutrition of this structure and predispose it to yield more readily, the direct cause of the corneal disease is infection from the microörganisms which have their nidus in the profuse purulent secretion, upon the recognition of which depends the rational and efficient treatment of this disease. This consists, first of all, in the removal of the pus from the conjunctival sac as soon after it is secreted as possible; and second, to render innocuous any portion of the secretion which remains in the eyes by appropriate germicides; and thirdly, to act upon the inflamed secreting membrane by some agent capable of modifying this surface and checking or diminishing its secretory activity for the time being.

The particular means adapted to carry out these indications are various, and the methods selected vary somewhat, according to the preferences of different physicians. To disinfect the conjunctival sac almost all the antiseptics employed in general surgery have been used, and with more or less good effect. The following plan has been found so efficient as to leave little to be desired: The attendant should remove the pus once every hour during the height of the disease; this can be done by gently separating the lids and flooding the conjunctival sac repeatedly with an ordinary pipette or dropper until the cleansing fluid returns clear and unmixed with pus. The fluid employed is a rather strong solution of bichloride of mercury, 1 : 2000. Besides its mechanical effect in flushing the sac and so removing the pus, it is one of the best germicides that can be employed and withal entirely safe. Other agents might be made use of, such as carbolic acid in two per cent. solution, saturated solutions of boracic acid, though the latter seems inert as a germ destroyer, at least according to laboratory experiments, nitrate of silver, etc., but none of these agents have any advantage over the bichloride. To meet the third indication, to modify the inflamed membrane, a rather strong solution of nitrate of silver, ten, twenty, or even forty grains to the ounce, should be applied once, or perhaps twice, in the twenty-four hours to the everted lids by the surgeon. The application can be readily made by wrapping a pledget of absorbent cotton around a match stick, dipping into the silver solution until saturated and then gently and thoroughly applying it to the palpebral conjunctiva. No subsequent washing with sodium chloride solution is necessary. The above treatment, simple as it is, gives results entirely satisfactory. I do not recall a single case in which it was practiced that did not result in perfect recovery without damage to the cornea, although in some cases the disease had

existed for a number of days and in a number of instances the cornea was so greatly infiltrated when the patient first came under treatment as to cause fears of immediate perforation. In those cases in which the cornea becomes affected, as evidenced by partial opacity, atropine, or, in some cases, eserine, should be instilled into the eye—for if, unhappily, perforation should occur, the eye will be more likely to preserve some degree of useful vision if prolapse of the iris can be avoided.

If one eye only is affected, the question arises how to prevent infection of the other eye. The shield, to protect the sound eye, is not applicable in infants as it is in adults. Great cleanliness, constant removal of the secretion, making the child lie on the affected side, will prevent infection in many cases. It might also be advisable to use the bichloride or the silver solution as a prophylactic measure.

Finally, in those cases in which perforation, with its usual results of adherent iris, etc., has occurred, something may be done by operative interference if any portion of the cornea remains clear. Here the indications are to free the iris from its adhesions to the cornea lest total staphyloma supervene. This procedure may be difficult to carry out, may involve extraction of the lens, and in any case would hardly give more than perception of very large objects. —(*For discussion, see Society Reports.*)

SOME MOOTED POINTS CONCERNING THE VOMITING OF PREGNANCY.*

By T. RIDGWAY BARKER, M. D.,

DEMONSTRATOR OF OBSTETRICS IN THE MEDICO-CHIRURGICAL COLLEGE, PHILA.; OUT-DOOR OBSTETRICIAN TO THE PENN DISPENSARY.

In discussing the etiology, symptomatology, and prognosis of the digestive disturbance associated with gestation known as morning sickness, or the vomiting of pregnancy, it becomes necessary at the very outset of a comprehensive study of the subject to exclude those forms of gastric trouble which, while often accompanying this purely physiological process, are nevertheless not dependent upon it for their existence, but upon some preëxisting morbid condition which is simply aggravated by the changes incident to gestation.

From a failure to appreciate and differentiate between these forms of gastric disturbance is largely due the confusion and misconception which is so general, hence the existence of such a multitude of views as to the cause and gravity of the vomiting of pregnancy.

It becomes necessary, therefore, that we state clearly that when we speak of morning sickness we do not include the so-called vomiting *in* pregnancy, but confine our remarks solely to the vomiting *of* pregnancy. Without further explanatory remarks, let us proceed to a consideration of the subject from a scientific standpoint, ever mindful, however, how easy it is to advance a theory and how difficult to find evidence to support it. That the occurrence of vomiting without apparent cause in females who have exposed themselves to the risk of conception is a sign of much importance is generally admitted, since it so quickly follows cessation of menstruation and, therefore, further tends to confirm the presumptive evidence of pregnancy. With reference to its etiology, one finds as many views as there are stars in the sky, each differing from the other in magnitude and brilliancy even as these distant orbs of light. Let us, then, turn away from such a merry-go-round of medical opinion and seek to discover the truth in the realms of anatomy and physiology rather than in the domain of idle speculation.

Coincident with conception, we find a general rise in the intra-pelvic blood pressure resulting in increased activity on the part of all the viscera therein contained which are concerned in the process of reproduction. Cells heretofore carrying on a passive existence now spring into a high state of activity. Likewise there occurs hyperplasia and hypertrophy of tissue which is especially rapid in the uterine muscular elements. Nerves, which in the unimpregnated condition possess but a low grade of sensibility, now become highly sensitive and transmit readily to their respective centres slight disturbances which under other circumstances would fail to throw them into a state of activity. What relation, one may very properly ask, exists between the vomiting of pregnancy and this exaltation of the nervous system? A causal one, most assuredly!

*Read before the Philad'a Co. Med. Soc., December 23, 1891.

Can one fail to realize that this is a symptom of pregnancy due to the change in the nervous equilibrium induced by the process of gestation? Surely not. Rather are the nausea and vomiting expressions of a reflex irritation, having its origin at the end-organs of the uterine nerves, which, as we have seen, are in a hyperæsthetic state. As the growing ovum demands, day by day, an increased space for its development, these end-organs are subjected to a varying degree of irritation, which is transmitted to the centres and thence reflected out along the nerve filaments distributed to the stomach. Why this affection is of more frequent occurrence and of greater severity in the first than in subsequent pregnancies one can readily understand by comparing the cavities of the primiparous and multiparous organs.

We find in the former that the uterine muscular walls are convex and nearly, if not quite, in apposition, hence the capacity of the organ in these females is relatively less. Not so the multiparous uterus, for its walls are concave and the capacity is further increased in length by one-half of an inch, owing to incomplete involution on the part of Nature after the first pregnancy. Need we seek for more conclusive evidence than this to support our position? Is it not plain to be seen that the resistance in the primiparous organ will be greater and the nervous disturbance more pronounced than where the cavity is larger, thus allowing the ovum to undergo its development without interference? Further, the period when nausea and vomiting are most apt to occur is in the second month, at a time when the growth of the uterus is principally lateral and the villi of the chorion are thrusting themselves into the serotine or placental decidua. As to the character of its onset, it is usually gradual, and disappears in a similar manner as the uterus rises out of the true pelvic cavity, thus having quite ceased by the end of the fourth month.

Concerning the symtomatology of this affection, it has not a few well-defined characteristics. The primary nausea and oppression experienced over the epigastrium soon gives place to vomiting, not, however, preceded or accompanied by any degree of nervous depression, as is the case with emesis under all other circumstances. The food, if any is present in the stomach, is expelled, not violently nor with any amount of retching, but almost as if it were regurgitated. Should the stomach be empty, then simply a little clear, normal gastric mucus is raised, which, as it usually occurs early in the morning, has given rise to the popular appellation of morning sickness. Further, if the matter vomited be food, it will not be found on examination to be sour or to have undergone decomposition, but in a more or less perfectly digested state, depending upon the length of time since its ingestion. As to the subsequent amount of nervous depression, in most instances it is practically *nil*, even when the vomiting is frequent and of long duration. This fact is very noticeable in some cases; the pregnant female may have just finished a hearty meal—for impairment of the appetite is rather the exception than the rule—when almost immediately afterward she will be obliged to evacuate the stomach, only to turn to the piano and find consolation for her lost breakfast. Rarely does one meet with a case of vomiting of pregnancy where the female's health has materially suffered, and this is what one would reasonably expect from the study of the symptomatology of the affection.

That this digestive disturbance is a purely sympathetic one, is proven by the fact that by a strong effort of the will the female can not infrequently ward off an attack.

Should she, for instance, have accepted an invitation out to dine during this period of gestation, she can control the nervous irritability by a firm determination not to betray her condition to the assembled guests. It has been repeatedly asked, How can a woman suffer from morning sickness at one period of gestation and not at another? In other words, How is it that the attacks vary in severity in different pregnancies? Moreover, Why is it that one pregnant woman has morning sickness and another does not? Can this be explained on the hypothesis of reflex nervous irritability? Most assuredly!

The variability in the duration and severity of the affection is due to two factors: Greater or less irritation, and greater or less irritability. The question may here be asked, Is vomiting of pregnancy a physiological or a pathological process?

It has been stated that among women of a strong, robust type, vomiting of

pregnancy is exceptional rather than the rule, as is the case in Europe and America. But this fact has no direct bearing on the case; it goes without saying, that the stronger and less sensitive the nervous system the less general and severe will be the sympathetic disturbance. One certainly is not warranted in stating that the vomiting of pregnancy is a pathological process, for it is due to a purely physiological cause. There exists no morbid alteration in structure or function of the nerves. The irritability is not pathological but physiological, depending upon the degree of sensibility of the nervous apparatus. Yet it has been claimed by some investigators that this very exaltation is evidence of some pathological lesion. Surely not. It were, it seems to me, as reasonable to declare a person's brain diseased because he is irritated by Wagner's music, in which he finds no harmony, as to declare that the sympathetic disturbance excited by pregnancy is due to some morbid process.

Again, if we select two galvanometers, one registering the weakest electric current, the other equally well constructed, but less sensitive, we cannot say that the former is any more perfect than the latter; they differ simply in the degree of their sensibility. Difference in sensibility within certain prescribed limits is a physiological, not a pathological fact. While vomiting, as Austin Flint points out, is not, strictly speaking, a physiological process, yet under these circumstances it is far from pathological; rather let us say it is the pathological expression of a physiological process. The vomiting of pregnancy, unless complicated by some morbid process, never gives rise to alarming symptoms or threatens life. If prolonged beyond the period of quickening, its continuance may be accepted as positive evidence of some complication, which a decided alteration in the character of the vomited matter will usually indicate.

Cases of pernicious vomiting call for diligent search for organic lesions in the nervous system, or structural changes in some of the generative or associated organs. That the vomiting of pregnancy occurs in healthy, strong women almost as frequently as in their less robust sisters, though in a milder form and of shorter duration, only confirms the view as to its physiological nature. The view advanced, that the difficulties of parturition are proportionate to the severity and length of the morning sickness, one is scarcely prepared to accept. The gravity of the digestive disturbance is to be estimated by the amount of nervous irritability, while the difficulties attending parturition may be classified under two heads: maternal and fœtal. The former including uterine inertia, pelvic deformity and rigidity of the soft parts; the latter abnormal size of the fœtus and malpositions of the fœtus. Surely no such conclusions are justified, for the reports from the large lying-in hospitals of both America and Europe unmistakably prove no such relation exists. Females who have suffered great annoyance from morning sickness have frequently as easy and sometimes more rapid labors than those who have almost wholly escaped this unpleasant early indication of pregnancy. Therefore, in conclusion, it would appear from a study of this affection: First, that the vomiting of pregnancy is due to a reflex irritation produced by the developing ovum acting upon an exalted nervous system. Second, that it is not an affection of great gravity and need occasion no anxiety or alarm. Third, that active treatment is rarely demanded, as it is only a disturbance of a few weeks at the most. Fourth, that the severity of the gastric trouble is no indication of the character of the subsequent labor. Fifth, that where the affection persists beyond the period of quickening, it is due to pathological causes, which must be discovered and treated accordingly. (*For discussion, see Society Reports.*)

CASE OF INVERSION OF A NON-PUERPERAL UTERUS.*

By JOHN B. ROBERTS, M. D.,
PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

This case seems to me of interest because of the comparative rarity of the condition. I give it simply as a contribution for clinical discussion.

' Mrs. H., aged forty-three, in November, 1890, complained of having had bearing-down pain for some months, and a slight vaginal discharge which had recently become offensive. Menstruation had been regular, and there was no great loss of blood

* Read before the Philadelphia County Medical Society, December 23, 1891.

at her usual periods. The woman had been married eight years; had had one miscarriage, but no children.

"Vaginal examination revealed a reddish mass protruding from the uterus through a well-dilated os. As this was evidently a submucous fibroid tumor, a drachm of fluid extract of ergot was ordered to be taken three times a day, and douches of corrosive sublimate (1:4000) to be used twice daily. A little later the vaginal douche was changed to carbolic acid solution.

"About ten days after I first saw her the patient was etherized, and a sloughing, friable mass removed with the fingers and forceps, aided by a curette. The mass was about the size of a small orange. The patient recovered promptly and was discharged from treatment in about two weeks' time.

"Three weeks later I was sent for to see the same woman, who was then very emaciated, exceedingly week, and suffering intense pain in the abdomen, with the knees flexed upon the pelvis, and with an exceedingly fetid, profuse, and sanguinolent discharge from the vagina.

"Pressing my hand upon the abdomen, I found the bladder greatly distended with urine, and upon investigation I discovered that she had not passed any water for several days. Catheterization relieved this condition, and examination by the vagina showed the existence of another sloughing fibroid tumor. This was readily removed with the forceps and fingers. The patient recovered promptly, though she was still weak when last seen.

"About three months later she came to my office exceeding pallid, with the statement that for some time she had been suffering from most profuse uterine hæmorrhages. Examination revealed protruding from the vulva a mass about the size of a small apple. Constant loss of blood was taking place, and the patient was so anæmic that she nearly fainted in my office, and had to be sent in a carriage to the Polyclinic Hospital. The vagina was packed, and the patient given full doses of quinine and whiskey. This was in March, 1891. After having been kept in bed for several days she was etherized, and a full examination of the uterine condition made. I found what I had previously suspected—a small growth attached to the fundus of the uterus which had caused inversion of that organ. The mass occupying the vaginal outlet and the vagina was, therefore, the uterus, which had been turned inside out, with the attached polypoid, fibroid tumor. I readily tore loose from the mucous membrane of the inverted uterus what was found to be two small fibroid tumors, one about the size of a black walnut, and the other rather smaller. They are shown on the plate containing the specimens, but are now shrunken from long immersion in alcohol.

"An effort was then made to replace the inverted uterus by continuous pressure made with the finger introduced into the vagina. This was continued for a long time, but proved ineffectual. I considered at the time the propriety of removing the inverted uterus by performing partial or complete vaginal hysterectomy. It seemed to me, however, that it would be wise to make a further attempt at replacement before adopting radical measures. The patient was accordingly kept in bed nearly two weeks in order to build up her general health by stimulus and tonics, before making further attempts at invaginating the inverted uterine walls.

"She was then again etherized, and a prolonged effort was made at replacement by means of the fingers and Aveling's repositor. The manipulation was kept up for an hour and a half, but was absolutely useless, although the pressure was made in a very continuous manner. The patient became so weak that I feared she might die upon the table, and I therefore abstained from further manipulation and again put her back to bed.

"Two weeks later another effort was made to overcome the inversion of the womb. I was assisted on this occasion by Drs. Baldy, Baer and Anna M. Fullerton, whose counsel and aid I felt that I greatly needed. The abdomen was opened by a median incision, when the coils of intestine occupying the pelvis were seen united by recent lymph, evidently due to the traumatism of the previous manipulations. An endeavor was made to correct the condition of the uterus by means of strong forceps introduced through the abdomen to dilate the uterine neck, while pressure from below was made with the fingers in the vagina. Although these manipulations were performed by such skillful operators as those I have mentioned, we were unable to make any marked impression upon the displaced organ. Unfortunately, I had not provided myself with the most approved form of forceps. I then pushed through the fundus of the uterus a large needle carrying a strong piece of fishing-line to which was attached at the vaginal end a button of soft metal. I hoped that traction on this cord through the abdominal wound would, by means of the button pressing upon the mucous membrane of the uterus in the vagina, cause the uterus to assume its proper condition. While dilatation of the inverted fundus was made by means of the forceps, traction was made upon the string and pressure upward through the vagina. The muscular contraction of the uterine neck, however, prevented anything being gained by this manipulation, although the force applied was such as to finally cause the button to pull through the fundus of the uterus and to make its exit into the pelvis. After spending considerable time in these unsuccessful attempts, I finally did a partial vaginal hysterectomy, removing the inverted portion high up and stitching the edges of the uterine wall at the fundus together. This procedure was resorted to only after the patient had been under ether for three hours and was so overcome by shock that her condition was extreme. She did not react, her temperature not rising above 95° F., and she died within a few hours.

"The abdominal wound was then opened, and a very small amount of blood found near the stump of the uterus. Evidences of non-septic traumatic peritonitis due to the previous manipulation were present, as has been stated in the account of the last operation."

In looking back upon this case, I cannot but feel a sense of regret that the more radical operation of vaginal hysterectomy was not done at the time that the patient was subjected to operation for removal of the tumors causing the inversion. My desire to avoid an operation accompanied by shock and hæmorrhage at the time she had been so depressed by violent and repeated flooding, made me adopt what at the time seemed a less radi-

cal course. The extreme difficulty of dilating the uterine neck in cases of inversion was not appreciated by me until I found my attemps at replacement futile. (*For discussion, see Society Reports.*)

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 9 and 23, 1891.

THE PRESIDENT, JOHN B. ROBERTS, M. D., IN THE CHAIR.

Dr. T. B. Schneideman read a paper on "Ophthalmia Neonatorum as a Cause of Blindness." (See p. 129.)

DISCUSSION.

DR. GEORGE E. DE SCHWEINITZ: Unfortunately, I came into the room too late to hear the first portion of this paper. There is no question that bichloride of mercury, under ordinary circumstances, is an excellent germicide, but in spite of the good results which have been reported, I am very much against the use of strong solutions of this drug in ophthalmia neonatorum. It is true that investigations have shown that a solution of 1 : 10,000 will retard the vitality of certain bacteria—for example, staphylococcus pyogenes aureus; but in ophthalmia neonatorum and in gonorrhœal ophthalmia, the characteristic behavior of the gonococci is their residence within the living cells, and under these circumstances I do not believe it is possible for irrigations of bichloride of mercury to act in their ordinary germicidal function. Moreover, I am convinced from clinical and direct histological experience that strong solutions of sublimate have a distinctly deleterious effect. I need not refer at any length to the disastrous results to the cornea that have occurred from the use of this drug in strong solutions during cataract operations. Especially is this true when they have been employed to irrigate the anterior chamber. It is of the highest importance during ophthalmia neonatorum that the epithelial surface of the cornea shall be kept intact; and while I am not prepared to say that the use of a strong solution can actually produce an abrasion, I am well satisfied that it adds distinctly to the dangers of the case. A recent European investigation in regard to the effect of this drug upon the cornea has demonstrated its capacity for producing changes that might well make one hesitate in its employment in very active strength. It should be remembered that during the height of an attack of ophthalmia neonatorum, the resisting power of the cornea is materially decreased, and hence very irritating solutions, no matter of what composition, are to be deprecated. I beg to be understood in this matter; I do not for one moment dispute the value of bichloride in purulent affections of the conjunctiva, but I deem it inadvisable to use the drug in strong solution, and believe that it is impossible to employ it *safely* in such strength that it will act as a *true germicide*. Moreover, it has been shown that bacteria in the presence of albumen have the power to reduce bichloride of mercury to calomel. Now, calomel, to a certain extent, is a germicide, but must have very inferior qualities under these circumstances. There does not seem to be any objection, for cleansing and antiseptic purposes, to a strength of 1 : 10,000 (Cohn, in his recent book, recommends (1 : 5000). A convenient strength is a grain to the pint—*i. e.*, about 1 : 7500. In the Philadelphia Hospital, as my colleague, Dr. McKelway, will testify, we are in the habit of using alternately a solution of bichloride of mercury, a grain to a pint, and a saturated solution of boric acid. If the cleansings are made hourly, first one and then the other drug is employed. Boric acid is without germicidal value, but it is an excellent slightly astringent cleansing agent.

Referring to the other portions of the treatment advocated by the Doctor in his paper, I beg to agree with him most emphatically—*i. e.*, with his use of nitrate of silver. It should not be employed in the earlier stages, or in any stage in which there is much infiltration and the formation of false membrane; but when there is free secretion of yellow pus, when the lids are supple, when the conjunctiva is covered with hypertrophied papillæ and positive granulations, nitrate of silver, in the strength of ten to fifteen grains to the ounce, is the germicide *par excellence*. Applied carefully with a cotton mop, and properly neutralized, if strong solutions are employed, any irritating effect upon the cornea may be avoided. It acts in three ways: as a germicide, because it is at the same time a superficial caustic, destroying a layer of epithelial cells, and probably the bacteria which are contained within them; as an astringent; and as an alterative, using that term to imply its efficiency to alter the nutrition of a mucous membrane which is inflamed.

In regard to the other solutions which various surgeons have employed in this condition—carbolic acid, aqua chlorini, weak solutions of nitrate of silver, etc.—my experience is limited. They come to us endorsed with high authority. In regard to one drug, however, I wish to place myself on record—namely, pyoktanin. I hope that no one will treat cases of purulent ophthalmia in the newly-born with this drug.

Finally, I may say that, in my belief, the more or less continuous application of cold is of great value in the earlier stages. The essayist has referred to atropine and eserine, evidently giving his preference to the former drug, should corneal ulceration indicate its use. I would reverse the order and place eserine first, provided no iritic complication contra-indicates its instillation.

DR. CHARLES H. THOMAS: There is one suggestion growing out of what Dr. Schneideman has said which seems worthy of further amplification—that is, the question of some legal enactment which shall help to prevent the blindness which is so frequently the result of ophthalmia neonatorum. Such a law has been enacted by the State of New York, and there has been some attempt to establish one in the State of Pennsylvania. It seems to me that there is no place in the State of Pennsylvania where a movement with this object in view could be more effectively inaugurated than in this society. It is my hope that all who have heard this very able and true statement, will resolve themselves into a committee to further the enactment of such a law as has been suggested. There is no question as to the propriety of compelling midwives to report such cases, and I am not sure but that we

could go further with propriety and require medical practitioners to report these as well as other cases of infectious diseases. There are, of course, many physicians who should not be put to this trouble, but there are others who see but few such cases, and it would have a wholesome moral effect upon all to feel that this disease was dignified enough to require a report to the Board of Health.

Dr. Charles P. Noble: I will speak upon this subject from the standpoint of the obstetrician rather than from that of the ophthalmologist. There are several points which interest me. I am much pleased to find that so long ago as 1807, some one had insisted upon the fact that the treatment of *ophthalmia neonatorum* should begin with the mother. This has been insisted upon by various obstetricians, and I have myself long felt the importance of it. It has been a rule with me for years to pay attention to the question of vaginal discharges in pregnant women. If there is a free vaginal discharge, even though no complaint is made of its irritation, I have always made a local examination, and if vaginitis were found to be present, have insisted upon systematic local treatment. I think that this is a most important point, and one that is even more important than the early treatment of the eye. If we can prevent infection, we do not need the early treatment of the ophthalmia. Some years ago, when connected with the Lying-in Charity, I saw quite a number of cases, and I have had several in private practice. I may say that among these cases there was only one in which an eye was lost. This occurred in a syphilitic infant. In this case, Dr. Lautenbach acted as a consultant, so that the child had everything that ophthalmological science could do for it. The treatment used at the Lying-in Charity was frequent irrigation with a saturated boric acid solution. When the discharge was very free, it was used as often as every half hour, together with silver nitrate solution (ten grains), used twice daily. It was thought that advantage was derived, particularly when the swelling was great, from the application of cold compresses.

Speaking still from the standpoint of the obstetrician, I should advise that the practitioner always avail himself of the counsel of an oculist in the management of such cases. He will thus be saved the anxiety and regret of occasionally losing an eye and forever injuring the prospects of the infant.

On motion, the following committee was appointed to confer with the State Board of Health relative to this subject: Drs. T. B. Schneideman, C. H. Thomas, Benjamin Lee, Edward Jackson, G. E. de Schweinitz.

Dr. T. Ridgway Barker read a paper on "Some Mooted Points Concerning the Vomiting of Pregnancy." (See page 133.)

DISCUSSION.

Dr. Charles P. Noble: Dr. Barker prefaced his remarks by saying that he should not take up the matter from a theoretical standpoint, and that he would not present the theories held by others, but would study it from the standpoint of anatomy. I think, however, that the theory he advances, that the vomiting of pregnancy is reflex in its origin, due to the growth of the ovum, is a very old one. The are a great many theories to account for this affection. Among the most important is that held by Grailly Hewitt—namely, that the vomiting is due to induration or inflammation of the cervix or to flexion. Dr. Hewitt has gone very fully into the subject, and while we may not agree that this is the only cause of vomiting of pregnancy, yet anyone who has studied the large number of cases which he reports, cannot help but feel that there is a close relationship between exaggerated flexion of the uterus and also induration of the cervix due to inflammatory trouble and the vomiting of pregnancy. I have myself not infrequently seen this combination. I have also seen vomiting associated with more or less endometritis, and with induration and thickening of the cervix which was present before pregnancy took place. Again, the uterus may be more or less fixed by old inflammatory trouble, and when it becomes pregnant it is prevented from rising into the belly, as is usually the case, and in that way also the reflexes are increased. Again, we know that the uterus may be retroverted and caught under the promontory of the sacrum, and may then be prevented from rising into the abdomen, and may produce such reflex symptoms. I am satisfied that old inflammatory trouble in the pelvis has a great deal to do with the vomiting of pregnancy. It, however, simply acts to increase the reflexes from the uterus.

A more recent theory, and one supported by so eminent an authority as Kaltenbach, is that the vomiting of pregnancy is hysterical. I think that there is no doubt that a certain number of cases are due to hysteria. But I would not go so far as to hold that all cases are due to this cause.

There is no question that not only do we have as a result of pregnancy changes in the pelvis, but the whole body of the woman increases in size and undergoes changes. The entire vascular system becomes hypertrophied, and the heart also becomes enlarged. We know that pregnancy changes the entire form of the woman. The entire system is involved, and we can readily understand that congestion of the alimentary canal can be brought about. We all know that the nervous system in the pregnant woman is extremely irritable. It resembles the nervous system in children. For this reason, irritation from the pelvis which ordinarily would not be sufficient to cause reflex symptoms, can do so at this period.

The Doctor assumes that the reason why primiparous women are more apt to have vomiting than multiparæ, is because the uterus of the multiparous woman is larger, and therefore the growth of the ovum would not cause so much distention. There is no question concerning the fact, but the explanation is not satisfactory.

It is true that the uterus of the multipara is larger than that of the primapara. It is also true that the abdominal walls are more relaxed, giving a less degree of intra-abdominal and intra-pelvic pressure. The woman is better prepared for pregnancy, having already been pregnant. The mental condition is probably not so disturbed, and the emotions not so excited in the multipara. All these points must be considered. Moreover, it must not be forgotten that the uterus grows as well as the ovum, so that it is at least questionable whether the ovum distends the uterus. Does it not simply fill it?

It seems to me that the practical outcome of the whole matter is that, given a serious case of vomiting in pregnancy, it is the business of the practitioner to find the cause of the trouble.

Whether it is extrinsic purely—due to indigestion or uræmia; or whether due to excitability of nervous system or to hysteria; or whether some pelvic lesion is the source of irritation. If this plan of treatment were followed, better results would be obtained.

Dr. John B. Roberts reported a "Case of Inversion of a Non-Puerperal Uterus." (See p. 135.)

DISCUSSION.

Dr. Charles P. Noble: It has been my experience to see two cases of inversion of the uterus, and in both cases the attempts at reduction failed. The first case I saw at the Lying in Charity, and was, I think, a long-standing post-puerperal case. Manual reduction was tried, but abandoned for the reason that the uterus was soft and macerated. In this case the uterus was amputated and recovery occurred. The second case I saw with Dr. Kelly and was present at an operation in which he opened the abdomen. The abdominal neck of the inversion was dilated with forceps, and manipulations were made with one hand in the belly and one in the vagina, but the effort at reduction failed. In that case, Dr. Kelly took out the whole uterus, and the patient made a good recovery.

Speaking of the treatment, Dr. Roberts did not mention one method which has met with excellent results. It is the method of gradual reduction advised by Dr. Aveling. Constant pressure on the inverted uterus is made through a repositor, which is attached by elastic bands to a support about the waist. A large series of cases has been reported in which this method has been employed with almost universally successful results. Of course, in some cases the presence of adhesions will prevent the reposition of the uterus. The reasons for the success of this plan is plain. The problem is to overcome the resistance of the muscular tissue in the upper part of the cervix, and to make it relax and dilate. This tissue is resistant enough to tire out the muscles of the surgeon when attempting rapid reduction, but gives way before the steady action of the rubber tapes. It seems to me that in a case of any standing, attempts at rapid reduction are inadvisable, and are liable not only to fail but to do harm. It seems to me that in a long-standing case of inversion, the thing to do would be to pack the vagina with an astringent tampon, and afterward apply the gradual method of Aveling. If that did not affect reduction, the best thing would be to do a radical operation. The question arises whether it would not be better to remove the ovaries and tubes, which would bring about a cessation of the hæmorrhage. This would be a simple matter, and I think that reduction in the size of the uterus would take place. If this were not done, I think that a simple amputation of the protruding mass would be quite a feasible operation; but, of course, the danger there would be that after the mass of the uterus was removed the remainder would reinvert itself, and possibly infect the peritoneal cavity. This could be obviated by using transfixion pins. My own feeling would be in favor of removal of the tubes and ovaries, and later to do a vaginal hysterectomy, if necessary.

Dr. Roberts: In this case the uterus was not soft, but was as hard as a fibroid tumor. The tightness with which the neck grasped the inverted uteurs was something astonishing.

I am somewhat familiar with two other cases of inversion of the uterus. One happened some years ago in the country. The practitioner did not know what was protruding after labor, and sent for Dr. Levis, who, after a good deal of manipulation, pushed the inverted uterus back. The second was also, I think, a puerperal case, and happened not long ago at the Woman's Hospital of Philadelphia; in this instance, the physician was able, after manipulation for several hours, to replace the uterus. It was perhaps the knowledge of these cases which led me to make such prolonged attempts at reduction. I see now that it was unwise, and I agree with Dr. Noble that if such a case again came under my care, I should be inclined to first remove the ovaries, and if that were not sufficient, to make a total hysterectomy. This patient was *in extremis* at the time, and I did not feel justified in doing a too radical operation when I removed the two small tumors.

SELECTED FORMULÆ.

INTESTINAL ANTISEPSIS.

The following formula is recommended by Dujardin-Beaumetz as a good intestinal antiseptic:

℞ Salol,
Salicylate of bismuth,
Bicarbonate of sodium, āā 150 grains.
M. and divide into xxx powders in capsules. S. One before breakfast and one before dinner.

—*Les Nouveaux Rémèdes*, November 8, 1891.

RESORCINE IN DIARRHŒA.

Menckle (*Centralbl. für klin. Med.*) who has, with gratifying success, employed resorcine in the treatment of diarrhœa in children and adults, highly recommends the following:

℞ Pure resorcine.....gramme 1.
Distilled water.....grammes 90.
Simple syrup..... " 60.
Camphorated tinc. of opium....gramme 1.
M. S. A dessertspoonful every two hours.

For children b th the resorcine and the paregoric should be reduced to 0.50 grammes, and then the potion can be given in teasp onful doses every two hours.

—*Le Bulletin Médical*, November 11, 1891.

TUBERCULOSIS.

Arthaud proposes the following mixtures in the treatment of tuberculosis, especially in the second stage of the disease:

a. ℞ Iodide of potassium.....grammes 10.
Alcoholate of tannin..... " 20.
Glycerine..... " 150.
Alcohol..... " 50.
Banyuls wine.....q. s. for 1 litre.
M. S. A glassful after each meal.

b. ℞ Fluid extract of rhatany (50 per cent).....grammes 30.
Syrup of mulberries..... " 250.
M. S. A tablespoonful 5 times a day, to be accompanied by the administration, night and morning, of 10 drops of tincture of iodine in milk.

—*Le Progrès Médical*, December 5, 1891.

FUCHSINE IN CHRONIC ULCERS.

After washing of the ulcers with warm water, they should be touched with the following solution, as recommended by Rosenberg :

℞ Distilled water.....grammes 200.00.
Alcohol (90 per cent.)..... " 10 00.
Fuchsine..... " 0.70.

The ulcers are to be covered with gauze moistened in the same solution. The drug is said to diminish pain and suppuration, and to cause a rapid cicatrization.

—*Le Bulletin Médical*, November 11, 1891.

FOR FISSURES OF THE TONGUE.

The following solution is applied, by means of a pencil, in the treatment of fissures of the tongue :

℞ Phenic acid.....grammes 2.50.
Tincture of iodine,
Glycerine..... āā " 12.50.

—*Allgemeine med. centr. Zeitung ; Le Bulletin Médical*, Nov. 11, 1891.

LARYNGEAL AFFECTIONS.

Schnitzler recommends the following mixture to be blown into the cavity of the nose and of the naso-pharynx, as well as into the larynx, in diseases of those parts :

a. ℞ Subnitrate of bismuth.....grammes 10.
Sugar of milk..... " 10.
Balsam of Peru ..... " 2.
M.

The same author extols the following solution as a local application :

b. ℞ Chlorhydrate of cocaine.....grammes 0.50.
Balsam of Peru..... " 10 00.
Alcohol..... " 10.00.
Aromatic essence.....drops 5.

Schnitzler prefers the balsam of Peru to phenic acid, creasote or creoline, on account of its agreeable taste.

—*Revista de Ciencias Médicas de Barcelona*, December 10, 1891.

TOPICAL APPLICATIONS IN DIPHTHERIA.

Dr. George W. Peck writes in *The Medical News* that he has found the following to be an efficient application in the treatment of diphtheria. It can be employed in all stages of the disease, without danger to the patient. It should be applied often and thoroughly, by means of a brush or cotton swab, until the diseased membrane entirely disappears. In connection with this remedy he gives as much brandy as the patient will bear, and such other remedies as may be indicated :

℞ Acidi borici..... 3j.
Acidi lactici .....f 3j.
Glycerini.....f 3jss
Aquæ dest.....f 3ijss
Liq ferri subsulph.....f 3jss.
M. This solution may be used in full strength or diluted with water, as each case may require.

SULPHUR IN DISEASES OF THE SKIN.

Zadeck, of Kiew, who has made an especial study of the therapeutic uses of sulphur in cutaneous affections, recommends the following preparations :

For inveterate cases of *acne rosacea* and *seborrhœic eczema :*

a. ℞ Flowers of sulphur.....grammes 2.50.
Ointment of benzoate of zinc (or vaseline)..... " 30.00.
M. S External use.

b. ℞ Flowers of sulphur,
Spirit of camphor,
Glycerine,
Rose-water.....āā grammes 10.
M. S. To be applied over diseased parts, on retiring.

This is especially recommended in *acne rosacea* of the nose, and also of the face.

For *seborrhœa of the scalp :*

℞ Flowers of sulphur.....grammes 200.
Oil of sweet almonds..... " 90.
Glycerine..... " 90.
M. S. Externally applied ; to be shaken before using

For *hyperhydrosis* of the hands, axilla, feet and other parts :

a. ℞ Flowers of sulphur.....grammes 2.00.
Powder of arrow-root..... " 15 00.
Salicylic acid..... " 0.50.
M. S. To be powdered over affected parts.

b. ℞ Flowers of sulphur.....grammes 8
Sulphuric æther..... " 10.
Rectified alcohol..... " 60
M. S. To be applied over diseased parts.

—*Le Bulletin Médical*, December 16, 1891.

SYPHILITIC OTITIS.

Laurence Turnbull recommends the following prescriptions in the constitutional treatment of syphilitic diseases of the ear :

a. ℞ Red iodide of mercury.....15½ grains.
Iodide of potassium.....13 drachms.
Distilled water.....2 fluid ounces.
M. Dissolve and filter, then add simple syrup until the whole measures 50 fluid ounces S. One teaspoonful 3 times a day.

b. ℞ Bichloride of mercury..... ⅛ of a grain.
Arsenious acid..... ¼ "
Pyrophosphate of Iron .....6 grains.
M. and make xxiv pills. S. One pill 3 times a day.

—*Annals of Ophthalmology and Otology*, January, 1892.

TREATMENT OF SCABIES.

Prof. Kaposi, of Vienna (*Wiener med. Wochenschr. ; Gaceta médica catalana*, No. 7, 1891), recommends the following salve as most efficacious in the treatment of scabies :

℞ Adipis.....grammes 100.
Saponis..... " 50.
Naphthol, *B*..... " 15.
Cretæ pulverizat..... " 10.

The treatment should not necessarily extend over twenty-four hours. If there be pruritus present the amount of naphthol must be reduced ; and if eczema, still less must be used, as the naphthol determines an active irritation.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by **postal note, money order** or **registered letter.**

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER; For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

"The Medical and Surgical Reporter" stamped in gilt on the back.

PRICE, 50 CENTS.

LEADING ARTICLE.

THE ACTION OF ERGOT AS A HÆMOSTATIC IN UTERINE HÆMORRHAGE.

Whatever may be our knowledge at present of the physiological action and therapeutic value of ergot, it is certain that many essential points regarding this interesting drug remained to be clearly explained experimentally and clinically. Opinion appears to be equally divided on the question of the action of ergot upon the circulation, for in looking over the literature of the subject we come across a mass of evidence replete with contradictory statements.

Thus, for instance, in regard to the effect produced by ergotine on the arterial pressure: First, the researches of Vogt, Holmes, Kohler, Eberts and H. C. Wood, which seem to show a decided increase; second, the results obtained by Herzmann, Borescha, Madelin and Wernich, showing a lowering of pressure; third, the investigations of Markwald, indicating that the blood pressure is neither increased nor diminished.

It is well known that ergot or its essential alkaloid exercises in hæmorrhage a decided action; that is, under its influence the flow is checked. How this phenomenon is brought about has not been definitely established. Leaving aside, for the time being, a centric vaso-motor influence (an influence which, according to most authorities, is not exercised by the drug), and referring especially to the effects produced by the remedy on uterine hæmorrhage, it is apparent that the drug exerts an action on the uterine vessels and nerve structures. This appears to be sustained by the recent experiments of Ellinger. In normal conditions, it has been found that asphyxia causes peristaltic contractions of the uterus, that they are even observed in curarized animals, and that they are prevented by previous section of the spinal cord. Asphyxia under these latter circumstances is powerless to excite the organ into activity. On the contrary,

ergot, which, under ordinary circumstances, is able to act upon the uterus as an oxytocic, retains the same power after previous division of the medulla spinalis —an indication that the action of the drug is a peripheral one. Ergot acts, therefore, directly upon the spinal cord or uterus; that it is upon the latter seems evident in the fact that it produces contractions in the excised organ. This admitted, the drug, to diminish hæmorrhage, must directly influence the uterine muscular fibre itself or else produce constriction of the arterioles. Neither view, however, is accepted by Ellinger, and following the opinion of Markwald, referred to already, to the effect that under the influence of the drug the blood pressure remains intact, he regards the hæmostatic action of ergot under a new and certainly untenable light. He believes that the remedy acts upon the blood itself, rendering it coagulable at more or less susceptible points of the vascular system.

The most recent and a very valuable contribution to the study of the actions of ergot is that of Hemmeter, published within a few months. The experimental investigation was carefully carried out by the author, and from the results obtained he finds, among other facts, that ergot increases the blood pressure, diminishing at the same time the number of cardiac pulsations. The increase was generally preceded by a primary fall of pressure, the unusual rise occurring not only in normal animals but also in those in which the heart was previously isolated from all nervous connection by section of the pneumogastrics and spinal cord. These results appear to corroborate those observed by Holmes, Eberts, Wood and others, and it is evident that the rise of arterial pressure is dependent upon an action of the drug on the heart or on the arterioles. From a purely physiological point of view, if the arterioles are made to contract, the blood pressure rises, but, at the same time, the increased pressure stimulates the vagi centres in the medulla oblongata, in consequence of which the pulse-rate falls, and thus we have the curves of the pressure and the pulse running in opposite directions. When this takes place it is assumed by physiologists that the change in the pressure is due to the arterioles. This is precisely what occurs under the influence of ergot, according to Hemmeter, and he, therefore, concludes that the drug produces an increase of the arterial pressure by an action upon the arterioles and not upon the heart.

Practically we know from clinical experience that ergot is not only an excellent oxytocic, but a most valuable hæmostatic; that it does good in almost all kinds of hæmorrhages. But the question at issue, whether this influence is due to an action of the drug on the arterioles, as is generally held, or whether it is due to an alteration on the blood itself, as is believed especially by Ellinger, remains unsettled, although it seems clear that the view of Ellinger is incorrect.

THE VISITING NURSE SOCIETY OF PHILADELPHIA.

There is a little society in Philadelphia which is accomplishing, in a quiet way, a most important and noble piece of work, and which deserves not only the hearty support of the charitably disposed, but emulation in every city and town in the country.

The chief objects of the society, as stated in the little pamphlet recently issued, are: First, to give a good nurse for a short visit to persons of means who can afford to fully pay for this care, but do not require the entire time of a trained nurse; second, to send an "Outside" nurse to a family in moderate circumstances where the service can be paid, but where there is no one to attend the sick person; third, to provide fully trained nurses for the sick poor, that by skilled care recovery may be hastened, and contagion and other evil consequences avoided.

It is the desire of the society to work under the orders of physicians among such patients as are neither suitable cases for hospitals nor able to obtain proper care at home. The nurse will visit each case once or twice a day, as may be required, and in extreme necessity will remain all day when possible. A moderate charge is made for each visit. As the nurses make visits daily, it is impossible for them to undertake contagious diseases.

Special nurses are provided for obstetric cases.

The society hopes for the co-operation of physicians both to help the destitute and those in narrow circumstances, and to establish among them a higher standard of hygiene.

As an evidence of the good work accomplished, we find by the report of the society that during the five years of its existence there were attended 2818 cases, and 35,703 visits made.

Nurses are furnished under the following terms:—

1. A *visiting* nurse is furnished without charge to those unable to pay for her service.

2. From those able to give the car fare, it is expected, being ten cents a visit.

3. For those in comfortable circumstances a visiting nurse can be furnished, but the charge must, in such cases, fully cover the expense to the society, fifty cents or one dollar a visit, according to the time required.

4. The "Outside Nurses" mentioned in this report must be paid by the patient according to agreement, as the society has no connection with them except keeping their names on file.

5. Visiting nurses will remain with a patient for the first twenty-four hours after a major surgical operation, and will visit after that daily as required. Should a patient need continuous care, an outside nurse must be engaged and paid for by the patient.

6. The hours of the nurses are from eight o'clock in the morning until eight at night. After that time they cannot respond to calls.

7. The nurses will visit in the morning those cases which have been reported the previous day, while those coming to the office before twelve o'clock will receive attention that afternoon.

8. The nurses are for the use of the public, and it is desired that physicians and others interested in the sick shall send for them. The service should be paid for whenever possible, as the society is supported entirely by charity.

We hope that the evident need of such a society in every large community, and the splendid work that has already thus been accomplished in this city, will be the means of stimulating others to follow in its footsteps. It is only when we or those near and dear to us are very ill, and need skillful attention, that we fully appreciate the invaluable offices of the Trained Nurse—the greatest luxury in medical practice of the century.

BOOK REVIEWS.

AGE OF THE DOMESTIC ANIMALS: BEING A COMPLETE TREATISE ON THE HORSE, OX, SHEEP, HOG AND DOG, AND ON THE VARIOUS MEANS OF DETERMINING THE AGE OF THESE ANIMALS. By RUSH SHIPPEN HUIDEKOPER, M. D., Veterinarian (Alfort, France); Professor of Sanitary Medicine and Veterinary Jurisprudence, American Veterinary College, New York, etc. Illustrated with 200 engravings, 8vo, 225 pp. F. A. Davis, publisher (Philadelphia and London), 1891. Price, $1.75.

The appearance of this work is an incident of importance to veterinarians, and horse and cattle owners and dealers. It is the first existing treatise upon the subject in the English language.

The author, in the preparation of the book, states that he has "attempted to prepare such a book as he feels would have been of interest and service to himself in his association with animals as a layman, and would have aided his studies and appreciation of the anatomy of the teeth, dentition, and means of determining the age. He hopes, also, that this work will furnish to students and veterinarians, knowledge which will aid in surgical operations on the mouth."

He has drawn freely from the French, German and English sources, both in text and illustration. The book is well planned, clearly written and printed, and is an excellent exposition of the subject.

A, B, C OF THE SWEDISH SYSTEM OF EDUCATIONAL GYMNASTICS. A PRACTICAL HAND-BOOK FOR SCHOOL TEACHERS AND THE HOME. By HARTVIG NISSEN, Instructor of Physical Training in the Public Schools of Boston, Mass., etc. With 77 illustrations. 12mo, 107 pp. F. A. Davis, publisher (Philadelphia and London), 1891. Price, 75 cents.

In the teaching of Swedish gymnastics the author has found that the treatises on the subject for the most part are not sufficiently practical to be of use as a guide to inexperienced teachers. In the preparation of this little book he has avoided the use of technical terms, and has endeavored to furnish plain answers to the most frequent questions, besides giving directions and illustrative wood-cuts for exercises for children of different ages. The first two chapters contain questions and answers such as have been most frequently put to the author in his nearly fourteen years' experience as a teacher of gymnastics, and these two chapters will give a very satisfactory idea of the foundation of the "Swedish System of Gymnastics." Other chapters contain what are termed prescriptions for daily lessons arranged somewhat as follows:

Five daily orders of exercises for second and third class of Primary Schools. Six daily orders for the first class of the Primary Schools. Seven daily orders for the fifth and sixth class of the Grammar Schools. Nine daily orders for the third and fourth class and fifteen for the first and second class of the Grammar Schools. The book seems admirably to fulfill the purposes for which it was written.

TREATMENT OF BILIARY LITHIASIS.

Dr. Dujardin-Beaumetz (*La Sémaine médicale*, No. 51, 1891), employs as cholagogues:

1. ℞ Euonymin } ..... āā grammes 2 (grs. xxx)
Saponis medicinal }
Sufficient for twenty pills. Take one pill morning and evening.

2. ℞ Sodii salicylic.....grammes 15.
Aquæ..... " 250.
A dessertspoonful after each meal.

For the gall-stone colic one may try large doses of olive oil (200 grammes, —fl. ℥ vij—at a time). If this fail, then he advises hypodermic injections of atropine and morphine, according to the following formula:

℞ Morphiæ sulphat.....cgm. 10.
Atropiæ sulphat..... " 1.
Aquæ sterilizat.....grammes 20.
Inject a (Pravaz) syringeful of this solution.

PERISCOPE.

THERAPEUTICS.

COCA AS A PROPHYLACTIC AGAINST INFLUENZA.

Dr. Sajous writes in the *Satellite*: The nature of influenza, the marked debility induced by it, and its sequelæ, all point to a remarkable depression of the general system. During its presence in the country, the prevalence and severity of other acute diseases were largely increased and the mortality from all other causes augmented. This condition of affairs continued for some time after the subsidence of the epidemic.

The value of coca as a tonic to antagonize any tendency to adynamia is too well known to require elaboration here. Its therapeutical effects tend to build up precisely what influenza tends to destroy —a fact instanced by the use made of coca leaves by the natives of Bolivia and Peru, which renders them capable of undergoing the greatest possible physical strain, and that frequently with sparse nourishment. This remarkable tonic action of coca in medical therapeutics has further been tested by Brown-Sequard, Dujardin-Beaumetz, Bell, Bouchut, A. McLane Hamilton, A. E. McDonald, H. M. Lyman, I. N. Danforth, P. S. Conner, and many other eminent physicians, too numerous to mention in the space at our disposal.

TREATMENT OF ANGINA PECTORIS BY COCAINE.

In a paper in the *Revue de Médicine*, the author strongly recommends the use of cocaine in angina pectoris, in the dose of ½ to ⅓ of a grain three or four times daily. He quotes four cases of this disease which were benefited greatly by this treatment. If the attacks do not cease immediately after taking the remedy, they completely yield to it, however, in about three days. Under its use the pulse becomes slower but fuller, and the quantity of the urine is augmented. The author refers to some observations previously made by him, which appeared to show that the inhalation of oxygen in this disease did much good; he therefore suggests that it should be tried in conjunction with the internal administration of cocaine.—*Med. Chronicle.*

A NEW REMEDY FOR PHTHISIS.

Hardly a week passes without some fresh drug being proposed as an infallible cure for phthisis. This time the remedy is monochlorophenol, recently prepared by Signor Tacchini, a chemist of Pavia, and tried by Dr. Passerini, of Casate-Nuovo. The drug is a powerful antiseptic, free from the disagreeable odor and from the caustic and irritant action of the related compound, trichlorophenol. It is recommended as an inhalation in various affections of the respiratory passages, and particularly in pulmonary tuberculosis. Monochlorophenol is very volatile, giving off vapors much heavier than air, which are, it is supposed, able by their weight to penetrate even into the alveoli when inhaled. The drug is, according to Dr. Passerini, always well borne even in cases of advanced phthisis. Under its influence the sputa diminish in quantity and lose their purulent character; the bacilli become less numerous, sleep and appetite are restored, and body weight increases. A complete cure is reported in five cases after one or two months' use of the drug, symptoms being undiscoverable even five months after leaving off all treatment. We think we remember the same claim being made for other drugs, all of which have, however, after a brief reputation, fallen into the limbo of neglect.—*Brit. Med. Jour.*

THE TECHNIQUE OF MASSAGE.

The forms of disease to which Zabludowski directs attention with reference to the use of massage, are :

1. Traumatic neurosis, with scars from the original injury, productive of nerve disturbances, that is to say, cases in which an individual changed by disease, reacts in an abnormal fashion to the bodily ailment.

2. Affections of the peripheral nerves; (neuritis and perineuritis) especially of traumatic origin.

3. Nervous dyspepsia with constipation, increased formation of gas and tenderness of the abdomen, caused by displacement and pressure upon the intestines, with or without a floating kidney.

In cases of traumatic neuroses in which the simple touching the scar produces a severe pain. Z. recommends leaving the injured spot entirely alone at first.

One should begin the mechanical manipulation as far as possible from the scar and should work gradually from the centre toward the periphery. At each treatment gradually approach the neurotic field, and thus, in three or four treatments it will be possible to directly seize the scar without producing any irritation, which tends to the development of cramp or similar effect. In cases in which massage works very promptly, the result is to be explained by psychical influence. In diseases of the peripheral nerves (neuritis and perineuritis, paralyses of single nerves and muscles) which occur especially in the extremities, it is desirable to effect the reserptive processes, and to establish a "dynamic effect." Z. recommends here a method which enables us to influence the deeper structures without much irritation. This is intermittent pressure which is exercised by the hand of the masseur making centripetal rolling motions.

In conclusion Z. describes a method which he applies for constipation due to atony of the bowel, whether it be with general nervous phenomena, or with severe pain and distention of the abdomen, high fever and giddiness. Inasmuch as we have to do with a local mechanical obstruction to the movement of the intestinal contents, a mechanical treatment is naturally the one which first attracts attention. Z. conducts massage according to a method of his own, which requires the knee-elbow position.—*Review in Schmidt's Jahrbücher, p. 30.*

TREATMENT OF RINGWORM.

Kerley (*N. Y. Med. Journ.*, October 10th) advocates the following methods of treatment : Two grains of bichloride of mercury dissolved in a small quantity of alcohol are added to one ounce of equal parts of kerosene and olive oil. This should be thoroughly rubbed into the diseased areas, and the whole scalp thoroughly saturated once a day, until a smart inflammation is produced ; the part should then be covered with a simple ointment until the inflammation has subsided, when the treatment may be resumed, but the applications may be made less frequent and in a less vigorous manner. A variation in the treatment, which he sometimes found useful, was to rub into the diseased areas on alternate days with the above a saturated solution of iodine in absolute alcohol. In all cases the scalp should be frequently washed with soap and water. Slight inflamma-

tion of the scalp was induced in most of the cases, and in a considerable number a moderately severe squamous condition of the scalp followed on the cure. This was remedied by the application of a 3-per-cent. solution of resorcine frequently. This treatment effects a cure in from six to nine weeks.

KNEIPP'S WATER CURE.

Dr. A. Schleichner (*Zeitschrift für Therapie*) describes the system of hydrotherapeutics practiced by a priest named Pfarrer Kneipp in a small Bavarian village, who, like Priessnitz, has created quite a *furore* in Germany and has gained numerous adherents. Kneipp's system consists in certain hydro-therapeutic measures, the administration of simple household remedies, and the regulation of the patient's mode of living. To strengthen the nervous system, the patient is advised to walk on moist grass or in a bath-tub filled up to his ankles with cold water. The cold pack, consisting of several thicknesses of coarse linen, is employed in certain cases, the sheet being wrapped around the entire body from neck to groin or applied to the abdomen or back; it should not remain longer than an hour. As regards the use of baths, the cold foot-bath should last from one to three minutes; the warm foot-bath has a temperature of 99° F., and lasts from ten to fifteen minutes and is followed by a cold bath of half a minute's duration. A "half-bath" is administered by letting the patient stand, kneel or sit in water while the back and chest are washed; it should not last longer than three minutes. The sitz-bath is taken before going to bed; its duration may vary from one-half minute to three minutes. If taken warm, it may last for half an hour, and an infusion of herbs is usually added to the water. The full bath, according to Kneipp, is the more effective the shorter its duration, and is mainly indicated in febrile conditions. The warm full bath has a temperature of 90° to 99° F., and consists of an infusion of pine-needles. It is followed by cold affusion or washing of the body with cold water. Steam-baths are carried out in a primitive manner, the steam being supplied by a kettle of boiling water. The cold affusion is made with a sprinkling-can from which the sprinkler has been removed; the entire body, or simply the affected parts, may be acted upon; in weak persons the water should be tepid. Another favorite manner of applying water is to sponge the body or affected parts with a wet coarse towel. This procedure is best done in the morning and should not last more than two minutes.

Kneipp advises that the patient should drink whenever thirsty, but never large quantities of fluid at a time, and none during the meal. His materia medica consists of simple domestic remedies. As regards the dietary, he is opposed to excessive use of meats; does not interdict beer or wine in persons accustomed to their use, but thinks less favorably of coffee and tea. He urges an abundance of fresh air and exercise, and advocates coarse linen underwear in place of woolen garments.

TABULATED TREATMENT OF SYPHILIS.

Dr. Bontemps, in a paper read before the Société de Médecine d'Angers, gives the following table for the systematic intermittent treatment of syphilis:

Months—Years.	1st	2d	3d	4th	5th	6th	7th	8th	9th	10th	11th	12th
1st.....	M	M	I	M	R	M	R	M	I	R	M	I
2d.....	R	R	I	M	I	R	R	I	M	I	I	R
3d.....	R / S	M	I	I	R / S	R	I	I	R / S	R	M	I
4th.....	R / I S	I	I	R	R / S	I	I	R	R / S	I	I	

M—Mercurials; I—Iodides; R—Rest; S—Sulphur.

This table is based upon the methods of Fournier and of Martineau. Taken altogether, we find that there are ten months of mercurial treatment; twenty of iodide treatment; six of sulphur treatment, and eight months of rest. To my mind there seems to be too much time devoted to the iodides; a certain portion could be profitably devoted to the exhibition of the mixed treatment, and probably with benefit to the patient. Another point is the long periods of rest at the inception of treatment. I have found that the same amount of rest, divided into shorter periods, with correspondingly shorter periods of treatment included, is productive of better results and reduces to a minimum the tendency to extensive or destructive lesions.

ICHTHYOL IN PYROSIS.

Dr. Thör (*Norsk Magazin for Lægevidenskaben*, No. 5, 1891) has found ichthyol of use in pyrosis, the sour eructations disappearing after one to two one-centigramme (one-fifth grain) pills or capsules. No disagreeable side- or after-effects.

TREATMENT OF ESSENTIAL PAROXYSMAL TACHYCARDIA.

Dr. Huchard (*Rivista Clinica e Terapeutica*, No. 14, 1891), recommends physical and moral rest, lying upon the left side or the back, with the head low, slight compression of the right or left carotid. The chloride of methyl spray, vesicatories or the cautery may be applied to the back of the neck. During the attacks digitalis by the rectum, on account of the gastric intolerance, will be of service. Injections of caffeine or ether are useful in the cardiac weakness. Nitrite of amyl and trinitrine are contraindicated. During the intervals the patient should abstain from coffee, tea, liquors, exciting substances and tobacco. The general treatment is physical and moral rest, and the use of arsenic as a nervine. In tachycardia, with arterial hypotension, the writer advises the sulphate of quinine with ergot in the following formula:

℞ Quiniæ sulph. } āā gm. 4. (℥j).
Extr. aquos. secal cornut., }
Extr. nuc. vomic. cgm. 10. (grs. jss).
Sufficient for forty pills.
Two pills two or three times daily for fifteen to thirty days.

As a prophylactic, the writer recommends digitalin, taken morning and evening for three weeks, fifteen drops of a solution 1 : 1000 of crystallized digitalin.

TYPHOID FEVER TREATED BY YEAST.

Dr. M. B. Thomson, in a recent number of an Australian contemporary, records some notes of the treatment of cases of typhoid by yeast. In all thirty-seven cases were so treated. Ten were severe, the temperature reaching or exceeding 104°; eight moderately severe, temperature reaching or exceeding 103°; eleven were mild, although the temperature reached 103°; eight were very mild, the temperature never being above 102°. In all recovery took place without any relapse. This point is worthy of note, inasmuch as, according to Fagge, the average proportion of relapses is from two to eleven per cent.—*Med. Press.*

A VEHICLE FOR BISMUTH.

Dr. Taurence (*Gazzetta degli Ospitali*, No. 24, 1891), has experimented with various substances in order to find the best vehicle to keep bismuth in solution, and finds glycerine to best fill the requirements. Four parts of glycerine to one of bismuth may be employed.

MEDICINE.

SYSTEMATIZED DELUSIONS OF AMBITION WITH HALLUCINATIONS AND IDEAS OF PERSECUTION IN A CASE OF MENTAL DEGENERATION.

M. Magnan, in a recent clinic, showed the following case:

K., native of Holland, received a good education; had typhoid fever in childhood. At the age of 18, entered a military school; there submitted twice to be examined to pass for an officer. At the age of 27, married a woman who brought him 40,000 florins. Nothing especially occurred until 1883. The king's son had been dead for some years. The second son also died and there was no one to inherit the throne of Holland. At this time he had some doubts as to his birth and origin, and gradually convinced himself that he was the son of the king. He made a retrospective examination of his whole life, bringing up all incidents which would serve to strengthen his delusion. At this time he began to fear persecution.

In 1883, while singing in church, he was suddenly apprised of the illness of his son and upon arrival home found him dead. He was persuaded that his son had been poisoned. He made an examination and filed a complaint, notwithstanding that the doctor who attended his son stated that he died a natural death. He thought the governess ought to be imprisoned ten years. His conduct now became exaggerated. He bought a fine house in the country, began to bet extensively in lotteries and soon failed. His wife and children left him alone with the two gardeners. One night he heard the dogs bark and said he would go and see what was the cause. It was the son of the burgomaster, who he said had come to assassinate him. At another time he took purgative pills, had violent colic and said he had been poisoned. Often he would overhear conversation in the streets of the Hague: "Here is the son of the king." He addressed the king a note asking for an interview and went to Paris during the arrangement of his affairs. Each month he offered one hundred francs to the consul of Holland to prove how much he hated to be banished. These, with other delusions and hallucinations, characterized this case.

THE VALUE OF THE PHYSICAL SIGNS AT THE APICES OF THE LUNGS IN SUPPOSED INCIPIENT PHTHISIS.

It is a fact well known to physicians generally that in health the percussion note at the apex of the right lung may occasionally be of higher pitch than that of the left apex. An examination of one hundred healthy symmetrical chests by Drs. Fussell and Adams, on the other hand, shows that,—

1. A normal condition at the right apex may be considered a diseased condition.

2. A diseased condition at the right apex may be considered normal.

3. The normal disparity in favor of the right apex may mask diseased conditions at the left apex.

In the *University Medical Magazine* for June, 1891, these authors publish a tabulated list of one hundred cases, taken as they presented themselves at the dispensary of the University of Pennsylvania, the diseases for which these cases were under treatment having no influence on the condition of the lungs.

When it is taken into consideration that the usual site of tubercular infiltration is at the apex of the lung, and that among the first signs of consolidation of the lung are higher-pitched percussion note, increased tactile fremitus and vocal resonance, the importance of the determination of the value of these signs is at once apparent. Of course there are other signs of incipient phthisis; one of which, prolonged expiratory effort, is very suspicious of approaching consolidation, and is a phenomenon which is seldom misleading. It is in those cases where these other signs are absent, masked, or very slight that these variations spring into greater prominence. Again, undoubtedly, the higher-pitched note, when existing normally at the right apex, is perfectly resonant; it lacks the deadened quality noticed in commencing consolidation. Yet this difference in quality is hardest to distinguish in just those cases where the greatest doubt exists, so that practically this difference is of no use. It is of the utmost importance that signs which are perfectly normal should not be mistaken for those of diseased conditions. On the other hand, it is equally important that we do not overlook diseased conditions at either apex, considering the signs as those of health. In the incipient stage of phthisis, so vital is the diagnosis for the future of the patient, and so slight are the symptoms and signs, that every straw adds weight to the conception of the case. A positive diagnosis is demanded by patient and as eagerly sought by physician. The disease is presented in its incipient stage oftener to the practitioner than any other disease, as its symptoms and results are so well known to the laity. Hence, in the majority of normal lungs, we have conditions which at once add suspicion to our conception of cases in which incipient phthisis is feared.

In examining this table, consisting of the reports of the condition of fifty-eight men and forty-two women, we find that eleven, or eleven per cent., have the same percussion note at both apices; nineteen, or nineteen per cent., have slightly higher-pitched note at the right apex; and sixty-nine, or sixty-nine per cent., have markedly higher-pitched note at the right apex, while one was higher pitched at the left apex. In the ninety-two cases where vocal resonance was taken, ten showed no difference at the apices; fourteen showed slight increase at the right apex, and sixty-eight marked increase. In ninety-three cases where the tactile fremitus was taken, no difference was found in eleven cases, slight increase on the right side in twenty, while sixty showed marked difference. Two cases exhibited marked increase of fremitus at the left apex.

In pursuing the examination, as far as possible, the results were obtained separately by each observer, compared, and then obtained together. Many cases where slight variation occurred were verified in this manner. One observer percussed the chest, while the other listened in such a position as to be unable to tell which apex was being percussed. Any case in which there was any difference of opinion as to the existence of any variation was put down in the list as equal on both sides. All the ordinary rules of percussion and auscultation were observed. There was no desire to force cases into one class or the other; the attitude was simply to endeavor to find the exact truth on the subject.

Supposing a case to present itself with higher-pitched percussion note, increased tactile fremitus, and vocal resonance at the right apex, the question, of course, arises whether this is a diseased condition. One of three errors may be made,—

1. A normal condition at the right apex may be considered a diseased condition.

2. A diseased condition at the right apex may be considered normal.

3. The normal disparity in favor of the right apex may mask diseased conditions at the left apex.

It is accepted by physical diagnosticians that the larger size of the right bronchus accounts for the increase of vocal resonance and tactile fremitus, both being due to the same cause,—increased transmission of the voice-sounds. As to the reason of the higher-pitched percussion note at the right apex, there is less clear and united opinion. The note at the left apex ought, if anything, to be the higher pitched; the explanations of the contrary conditions existing are not satisfactory. One explanation is that the liver at the base of the right lung deadens the wave-sounds from the tissue above, while the hollow viscus, the stomach, serves more as a sounding-board for the left lung. The degree of tension of the thoracic parietes and of the lung-tissue itself may account for it, as the greater the tension the higher the pitch.

In conclusion, the authors affirm—

That higher-pitched percussion note, increased vocal resonance, and tactile fremitus are normal at the apex of the right lung as compared with the left; that this normal condition can occur in such a number of cases and to such a degree as to cause in many instances a diagnosis of consolidation at the right apex; that finally, in deciding doubtful cases, other signs besides these three are necessary to formulate a diagnosis; continued observation of cases, where other signs are lacking, being necessary to watch the possible development of actual disease.

The authors report in detail three cases, which illustrate the existence of these three possibilities of error.—*Therapeutic Gazette.*

STERILIZATION OF METAL INSTRUMENTS.

Immersion of instruments in antiseptic solutions, particularly the two per cent. carbolic, is not sufficient to thoroughly sterilize them. Thorough mechanical cleansing is the first thing to do. After use, the instruments are rinsed in common water and laid in a hot soda and soap solution, and with a brush carefully scrubbed. They are then washed again and polished with so-called "*putzstein*" and alcohol and rubbed with chamois, and once more washed off with the soda solution and carefully dried. To sterilize them the use of dry heat requires too high a temperature and too long time. Boiling in soda solution is much better. The apparatus of Schimmelbusch, as made by Lautenschläger, is used. From a small box a spoonful (10 cu. cent.) of soda is taken and put in a litre of water for use in the sterilizer. Hanging with the box are a litre measure, hour-glass and match-safe. The instruments are allowed to boil from five to fifteen minutes, according to their size. The wire tray containing the instruments is then removed and placed in a pan containing a solution of one per cent. each of soda and carbolic acid.

CHANGES IN THE KIDNEY IN PHTHISIS.

The condition of the kidneys in phthisis has never been fully investigated. Several observers have described a fibroid condition. Becquerel and Rayher concluded that Bright's disease was very frequently associated with tubercular disease of the lungs. Peacock, in one hundred and seventeen cases of kidney-disease, found 30.7 per cent. of phthisis. Frerichs found that out of forty-two cases of Bright's disease six also suffered from phthisis. Bamberger stated that the disease was found in fifteen per cent. of those suffering from kidney-disease. In the *Centralblatt für Allgemeine Pathologie and Pathologische Anatomie*, February 1, 1891, Dr. C. von Kahlden publishes his results on the same subject. He is of opinion that slight degeneration of the renal epithelium is almost always found in active phthisis. It may, however, be so slightly marked that it is only visible on microscopic examination, and even then may be easily overlooked. The kidney may be either normal in size or somewhat enlarged. Microscopically the following conditions are noticed: The surface of the organ is smooth and yellowish in color; the capsule peels easily; the cortex is usually slightly thickened, and also yellow in color; the medullary portion is pale. The microscopic changes chiefly affect the cortex, the parenchyma being first attacked. The epithelial cells undergo fatty degeneration, but are occasionally replaced by fresh epithelial cells. The interstitial changes are, therefore, secondary, and generally slight, and take

the form of a small round-celled infiltration, and some increase of the connective tissue. The glomeruli also take part in the degeneration. The cortex is not uniformly affected, but the changes take place in patches. These lesions are evidently chronic, as is shown by the thickened capsule, the atrophy of some of the glomeruli, and the changes in shape of the epithelial cells of the tubules, these being altered from a club form to a cubical or cylindrical shape. Clinical symptoms which accompany the renal degeneration are unreliable. Albumen in the urine is rarely present. The author states that the condition is one of a chronic parenchymatous nephritis, and thinks that it may be caused by the poisonous products of the tubercle bacilli. —*Lancet.*

THE CELLS OF THE SPLEEN AND HÆMOGLOBIN.

Dr. Nicolai Hohlein publishes in his inaugural dissertation at the University of Dorpat a series of experiments made in continuation of the researches of Aug. Schwartz and Nicolai Hoffmann at the Physiological Institute of Dorpat. The former had shown that the protoplasm of various cells both destroys hæmoglobin and regenerates it, and Nicolai Hoffmann found in a hæmoglobin solution, which had been decolorized by spleen cells, an albuminoid; while the same solution, treated with hepatic cells, gave no albuminoid reaction. The author chose spleen cells, mixing them with three times their volume of diluted hæmoglobin solution. Decolorization took place on the average after twelve hours, and the color was completely recovered in from sixty to seventy hours. The author was then able to confirm the following conclusions Schwartz had arrived at. To regenerate a molecule of hæmoglobin, it is necessary to bring it into contact both with the cells and the decolorized liquor. Regeneration occurs also when the decolorized liquor is brought into contact with fresh spleen cells, but in this case the coloring is not so vivid as when the same cells are used which caused the decolorization. If the solution which has been decolorized by spleen cells is brought into contact with liver cells, all power of recoloring by the former is completely and irretrievably lost. The molecule of hæmoglobin is mechanically taken up by the cell which decomposes it, and during the period of complete decolorization of the liquor within the cell it is regenerated. The author adds to these the following independent results of his experiments. In decolorization, as well as in the process of regaining color, the quantity of the hæmoglobin solution is of less importance than its concentration, as with a certain medium degree of the latter all effects of the spleen cells cease. Regenerated hæmoglobin is distinguished from the original by being decomposed with greater facility by acetic acid, by its bright color and energetic oxidation. The albuminoid in the liquor which has been decolorized by spleen cells is cytoglobin. During the stage of decolorization, as well as that of regaining the color, a continuous new formation of cytoglobin is observed. This new formation of cytoglobin also takes place when the spleen cells are mixed with a 0.6 per cent. solution of chloride of sodium, but is in this case not so marked as when a solution of hæmoglobin is used. The hæmoglobin solution loses and the cells gain iron during the decolorization of the former; the reverse process takes place when the solution regains its color.—*Lancet.*

RELATION BETWEEN ALBUMINURIA AND THE RENAL CIRCULATION.

Dr. V. Casaretti, of Pisa (*Rivista Generale Italiana di Clinica Medica*, August 20, 1891), describes some curious results observed by him in cases of cyclical albuminuria. The experiments described were based on a previous observation of Dr. Landi, who had found that in a case of this affection he could for a time arrest the albuminuria by causing slight disturbance of the renal circulation by means of bandages applied to the limbs. The present observations were made on two cases of cyclical albuminuria, and on a third which presented the clinical signs of nephritis with swelling of the face, etc., but without other renal history. In the last case albuminuria was constantly present, but in the two first it was absent in the early morning, only very slight after the first meal, and pronounced after dinner. Application of "expulsive bandages" to the limbs had a most remarkable influence on these phenomena, the albumen disappearing entirely from the urine while the bandages were kept applied in the cases of cyclical albuminuria, and being very considerably diminished in the more serious case. Not only this,

but the effect was observable within a very short time after their application. The excretion of urea also was markedly diminished. As the author remarks, the alteration of the renal tissue must be very slight in these conditions if such a trivial alteration of the renal circulation can so rapidly modify or abolish the symptoms. The method may, if further observation should establish the above results, prove a useful one both in diagnosis and treatment.—*Brit. Med. Jour.*

PAIN IN HEART DISEASE: CONCLUSIONS FROM THE STUDY OF 483 CASES.

Nothnagel (*Zeitschrift für klinische Medicin*, Vol. XIX. No. 3) tabulates 483 cases of valvular disease of the heart with reference to pain. Lesions at the aortic orifice were most frequently accompanied with pain, while lesions at the mitral orifice were the least affected. Sixty per cent. of the cases of regurgitation were accompanied by pain, while only seven and one-half per cent. of the cases of mitral regurgitation had painful attacks. Curiously enough the combination of mitral regurgitation with aortic regurgitation seems to reduce the percentage of painful cases, only eighteen per cent. of such cases having painful attacks. He calls attention also to the frequency of pain in cases of disease of the heart-muscle without valvular disease. He holds that in a case where the diagnosis is uncertain, the occurrence of pain in the cardiac region, while, of course, not making the diagnosis sure, is of the greatest moment in pointing toward heart disease. Cases of arterial sclerosis, with cardiac hypertrophy, are much more frequently accompanied by pain than other forms of this latter class.—*Univ. Med. Mag.*

SURGERY

RESULTS OF TREATMENT OF REDUCIBLE HERNIA BY ALCOHOLIC INJECTIONS.

The original *modus operandi* of Schwalbe, says Dr. Theodore Zangger in the *Lancet*, who introduced this form of treatment in 1871, is slightly modified by Dr. Steffen, of Regensdorf (Zurich). A 70 per cent. solution of alcohol was used, and from two to four grammes of this fluid were injected round the saccus herniosus (hernial sac) after reposition of the hernia. The treatment was ambulatory; first one or two injections a week were made, then at greater intervals. Before being dismissed from medical supervision the patient had to go without the truss which he used during the treatment. The time of treatment varied from one month to two years and a half or more. In 293 cases there were 83 (62 per cent.) cures, 6 (48 per cent.) improvements, 9 (9 per cent.) of negative results. A cure was considered to have been obtained when, at least one year after dismissal of the patient, the hernia was neither to be seen nor felt during coughing or under intra-abdominal pressure, and when the patients, most of whom belonged to the laboring class, had been at their usual work for six or seven months. In 10 per cent. of the cases dismissed as cured the hernia returned, owing to various causes. The age of the hernia (*sit venia verbo*) was not without influence as to the result obtained, as will be seen from the following list:—

Duration of disease.	No. of cases.	No. of cures.	Per-centage.
Hernia incipiens . . .	11	11	100
Date, a few days . . .	10	10	100
Under ½ year	44	41	93.2
" 1 "	45	41	91
" 10 "	120	101	84.2
" 30 "	52	34	65.4
Over 30 "	5	4	80
Date unknown . . .	6	3	50

Dr. Steffen comes to the following conclusions: About four-fifths of small and medium-sized reducible herniæ can be cured, the wearing of a truss becoming in most cases superfluous. The prognosis improves the younger the individual, and the shorter the time the hernia has existed. Incipient cases should, therefore, be treated by injections, and not left to the chance of a spontaneous cure under a truss. Ambulatory treatment, with pauses of from four to seven days, gives better results than daily injection whilst keeping the patient in bed. In most cases the patient does better to continue his usual occupation, wearing a truss during the time of treatment. This method is also adapted to herniæ which cannot be retained by a truss, the latter being able to be worn, and keeping back the hernia after a course of treatment. In a few cases only toxic effects (alcoholism, urticaria, vertigo) were observed. This method of treatment is not entirely without danger; but accidents will be rare if due care is taken and regard paid to the anatomy of the respective parts.

CAMPHORATED NAPHTHOL IN SURGICAL TUBERCULOSIS.

Jules Reboul (*Centralblatt f. Chirurg.*) brings forward a new antiseptic made by incorporating 100 parts of beta-naphthol with 200 parts of finely powdered camphor, and then carefully heating until complete melting occurs, for the treatment of tuberculosis of those parts accessible to surgical treatment. This camphorated naphthol is an oily fluid, insoluble in water, but miscible with alcohol, fats, ether and chloroform. It is decomposed by exposure to the air, the camphor evaporating and the naphthol becoming crystallized. Light decolorizes it, but it may be preserved in dark, well-stoppered bottles. It is not a true chemical combination, but is probably only a molecular union. The antiseptic qualities of the new antiseptic depend, to a great extent, upon those of the beta-naphthol. Its antiseptic qualities have been proven by means of culture, as well as by clinical experiments, by R. It has been used with good results as an irrigating fluid in joints, bony cavities, tendinous sheaths, cold abscesses in the pleural and uterine cavities; and in addition to an interstitial injection, by instillation in cases of tuberculosis of the bladder, and in the preparation of dressings and disinfection of instruments. No poisonous symptoms have been observed, although the undiluted fluid was employed.

STERILIZING DRESSINGS BY MEANS OF STEAM.

Steam is now almost universally used for sterilizing dressings. In regard to the use of dressings impregnated with antiseptics, it should not be forgotten that dryness is a greater hindrance to the growth of germs than are antiseptics, and that it is better to use absorbent aseptic material than non-absorbent antiseptically-prepared stuff that allows stagnation of the wound discharges. It is very doubtful whether material which has been through the many processes necessary for its antiseptic impregnation is as free from germs as is that sterilized by steam. The toxic action of the antiseptic also makes its use undesirable. In using a steam sterilizing apparatus it is better to have the steam enter at the top and escape below; it is quicker and more efficacious. Lautenschläger's apparatus is used by Von Bergmann. This is composed of an outer asbestos jacket and two inner copper cylinders, between which the water is held. When the lid is on, the steam ascends between the two inner cylinders and passes inside to the dressings from openings in the top; it escapes from an opening near the bottom. Heat is applied by a gas jet beneath the apparatus, and it goes up along the sides between the outer copper cylinder and the asbestos jacket to escape by holes at the top. The dressing is allowed to remain three-quarters of an hour, subjected to a heat of 100° C. In order to avoid handling and exposure, the dressings are placed in tin kettles or boxes, having openings at the top and bottom which can be closed by means of a slide. The openings are left uncovered and the apparatus and dressings placed in the sterilizer. When sterilized, the slides are shut and the box taken to the operating clinic for use.

AMPUTATION OF THE LEG UNDER COCAINE ANÆSTHESIA.

Dr. R. H. Cowen writes in the *Internat. Jour. Surgery* that having seen no recent report of major amputation in which cocaine hydrochlorate has been used, he presumes that surgeons generally are slow in following Corning's method. The following case is his own:

Artie McPhail, a negro track-hand, was knocked from a trestle forty-five feet high, sustaining a fracture of the lower portion of the tibia and the metatarsal bones. When he came under his care, ten days later, he found him with an enormously swollen ankle, and a large suppurating wound opening into the neighborhood of the joint. Being unable, on account of the tremendous amount of swelling, to decide the exact nature of the injury, and leaning to conservative surgery, he tried faithfully antiseptic irrigation and drainage. Finding, however, no improvement, an exploratory incision was made under cocaine, revealing complete comminution of the tarsal bones.

He now resolved on amputation. The negro was very much afraid of chloroform, and positively refused to take it. He decided to use cocaine. After applying the rubber bandage above the site selected for amputation, he injected the cocaine as advised by Wyeth, carrying the needle just under the skin, elevating its point, and injecting as the needle was

withdrawn. This was done in four places, by which means anæsthesia was rendered complete all around the limb. He now proceeded to dissect the flaps. Then one or two punctures were made into the muscular tissue, around the limb, penetrating the periosteum, the fluid being ejected as he withdrew the needle. The operation was then completed. At no stage of the procedure was there the slightest pain. The patient, who was afraid of a pin scratch and was badly frightened beforehand was perfectly satisfied with the result and much astonished "that it did not hurt him."

There were no bad symptoms either during or after the operation. On the fifteenth day after, he removed the dressing for the first time. Union had taken place by first intention, with the exception of a small spot left for drainage, which was not as large as one's little finger nail.

RESECTION OF THE SPINE FOR SPONDYLITIC PARALYSIS.

Kraske (*Langenbeck's Archiv.*, Bd. 41, S. 831) discusses this subject at length. He had occasion to perform this operation several times, but the results were not so successful as one would be led to expect from Macewen's article. Paralysis from pressure is the kind most apt to be benefited by operation, but is usually better treated by extension. In tuberculous disease, abscesses and granulation, tissue may form around the cord, constituting a pachymeningitis. The exudate may compress the cord and make it anæmic. Interference with the lymph and blood streams also occurs and may cause œdema. Circulatory disturbances can exist for a long time without causing an irreparable paralysis. When, as is rarely the case, the disease affects the arches instead of the bodies of the vertebræ, operation is indicated and will probably be followed by good results, The improvement which sometimes occurs in these cases without operation has been, in his experience, only temporary. This has made him more willing to resort to operative procedures. The first case operated on had disease of the arches. The results were brilliant. Sensation began to return the same day and in two days was normal. On the fourth day motion began returning, and in four weeks the patient began to walk. Two months later the paralysis returned, and the patient died of tuberculosis of the lungs seven months after. In a second case an exudate into the canal was found, but no good results came from the operation and the patient died eight weeks later. In two other cases granulation masses were found overlying the dura ; in one of these recovery was almost complete in two months ; he then relapsed and is now dying of tuberculosis of the lungs. The results in the other case were not so rapid, but were marked for a while and then remained stationary. Operation may be advised also in those cases of kyphosis in which treatment has proved useless, and in which the onset of the paralysis was rapid, and involved the bladder and rectum. These cases lead to a rapid death anyway, and if allowed to remain long, the paralysis is irreparable.—*Univ. Med. Mag.*

A NEW OPERATION FOR SPASMODIC WRYNECK, NAMELY, DIVISION OR EXSECTION OF THE NERVES SUPPLYING THE POSTERIOR ROTATOR MUSCLES OF THE HEAD.

W. W. Keen, M. D., has devised and performed the following operation in view of the implication of the posterior muscles of the neck (*Annals of Surgery*, January, 1891) which rotate the head in cases of spasmodic torticollis. The operation consists of the following steps :

First Step.—The field of operation having been shaved and disinfected, make a transverse incision about half an inch below the level of the lobule of the ear, from the middle line of the neck posteriorly, or even slightly overlapping the middle. This incision should be two and a half to three inches long.

Second Step.—Divide the trapezius transversely.

Third Step.—Dissect up to the trapezius and find the occipitalis major nerve as it emerges from the complexus and enters the trapezius. In the complexus is an intra-muscular aponeurosis. The nerve emerges from the complexus at a point between this aponeurosis and the middle line, usually about a half inch below the incision, but sometimes higher up, and then enters the trapezius. It is always a large nerve of the size of a stout piece of catgut, and it is easily found if sought for at the right place.

Fourth Step.—Divide the complexus transversely at the level of the nerve.

This division should be made by repeated small cuts, so as not to cut the nerve which is our guide, after which dissect the nerve still further down from the anterior surface of the complexus, where it arises from the posterior division of the second cervical. Cut, or better, exsect a portion of the posterior division before the occipitalis major arises from it, so as to catch the filament to the inferior oblique muscle. This divides the *second cervical.*

Fifth Step.—Recognize the inferior oblique muscle by following the sub-occipital nerve towards the spine. The nerve passes immediately below the border of the muscle.

Sixth Step.—Recognize the sub-occipital triangle formed by the two oblique muscles and the rectus capitis posticus major. In this triangle lies the sub-occipital close to the occiput. It should be traced down to the spine itself, and be divided, or better, exsected. This divides the *first cervical.*

Seventh Step.—An inch lower down than the occipitalis major, and under the complexus, is the external branch of the posterior division of the third cervical to the splenius. When found it is to be divided or exsected close to the bifurcation of the main trunk. This divides the *third cervical.*

A drainage-tube and horse hairs are to be inserted, and as the patient lies on the back, although the wound is very deep, the condition is most favorable for good drainage. If desired, the posterior muscles can be united by buried sutures, independently of those in the skin. The after-treatment is the same as for ordinary operations.

OBSTETRICS.

CÆSAREAN SECTION FOR A GIANT INFANT.

Rachel and Neumer (*Répertoire d' Obstét. et de Gynéc.*, May 25, 1891) report the case of a woman, forty years old, the abdomen of whom, in the twelfth pregnancy, was enormously distended. The labor not progressing, version was attempted, but the fœtus would not pass the superior strait. Disarticulation of the leg, preparatory to evisceration, was attempted, but was unsuccessful. Finally, Cæsarean section was decided upon. The mother died soon after the extraction of the fœtus. The latter, almost exsanguinated as a result of the amputation, weighed twenty-two and a half pounds. The parents were not unusually large. The only explanation of the great size of the fœtus lay in the age of the mother and the number of pregnancies and in the fact that the fatal pregnancy had passed one month beyond term.—*Lyon Medical*, July 12, 1891.

PERFORATION OF UTERUS BY SOUND, AND FATAL SUBLIMATE POISONING.

Dr. Gebhard (*Nouvelles Arch. d' Obstét. et de Gynéc.*, August, 1891), recently observed a patient who had been under treatment from November 5th, 1890, for gonorrhœa. A 1 in 5000 sublimate solution was thrown up by means of a Bozeman's sound, at intervals of a day or two, in the out-patient room. On the third occasion, November 11th, immediately after the introduction of the sound, the patient complained of pain. After nearly a pint of the solution had been thrown up, the pain increasing, the injection was suspended. Vomiting and faintness came on rapidly. Perforation of the uterus and entrance of the solution into the peritoneal cavity was diagnosed. An opium suppository was administered. Dysenteric diarrhœa followed in a few hours. On the next day complete anuria set in. Mucus was continuously discharged from the rectum, which protruded and was ulcerated. Stomatitis with a trifling amount of salivation began on the third day. The patient died on the eighth day. Acetate of potash was given to promote diuresis, but completely failed in its object; pilocarpin caused profuse concentrated perspiration, which exhausted the patient and irritated her skin. Opium had been suspended early in the course of the case, Dr. Gebhard believing that it was contra-indicated in dysentery. At the necropsy two complete perforations of the fundus uteri were found, lying close together near the right tube. The peritoneum was inflamed; the entire large intestine and four inches of the ileum were ulcerated and in parts sloughy. One ulcer had perforated the sigmoid flexure. In the tubuli uriniferi were found cretaceous deposits of the kind described as occurring in the kidneys of patients dead from mercurial poisoning. Dr. Gebhard dwells at length on the pathology of this condition. It appears certain that stoma-

titis and salivation, which follow so sharply on an overdose of mercury by inunction or friction, are not the first symptoms in poisoning by mercurial injections used after child-birth. In that case diarrhœa is the earliest sign, and it rapidly becomes mucous, sanious, and ultimately fœtid. It represents gangrenous dysentery. The next symptom is a marked diminution in the excretion of urine, often ending in suppression. Stomatitis follows third, and may be severe, but salivation is not constant even in fatal cases. The temperature is subnormal. In the case above related, where there was acute traumatic peritonitis at the beginning, the temperature was high for a few days, but fell below normal when the symptoms of poisoning began to predominate. Erythema is rare.—*Brit. Med. Jour.*

URETHRAL CARUNCLE.

Christopher Martin (*Birmingham Medical Review*, September, 1891) thinks this neoplasm has hardly received the attention it deserves. He classifies it amongst the vascular tumors. It is exceedingly doubtful whether the connection between the majority of causes usually assigned to it and the disease is more than accidental. On the other hand, he thinks it likely that in many cases the exciting cause is a highly acid or irritating condition of the urine. Uric acid is peculiarly responsible for many cases. At the end of each act of micturition a drop of highly concentrated urine loaded with sharp crystals is left at the meatus. The crystals settle on the mucous membrane, and possible lodge in the glandular crypts which are so abundant there, and the repeated irritation of their presence determines the new growth. This irritation is partly mechanical, partly chemical. Whether or not it actually causes it, certain it is that, after the growth has developed, a highly acid urine frightfully aggravates the patient's sufferings. The great symptom is pain. The suffering is out of all proportion to the size of the growth. The distress is present on walking, passing urine, during coition, or at any time the parts may be impinged upon. The diagnosis is made complete on inspecting the external genitals. On drawing apart the labia, there is seen at the meatus urinarius, or just within it, a small bright crimson growth. It varies in size from a pin's head to a cherry, but is generally about the size of a pea. It is usually situated on the posterior lip of the meatus. It is very soft and friable, and bleeds readily on manipulation. If carefully prepared sections of a caruncle are examined with a moderate power, the growth is seen to consist of very numerous and widely dilated capillary loops embedded in a delicate connective-tissue stroma. The treatment consists in the *complete* removal of the growth. The patient is anæsthetized and placed in the lithotomy position. An elliptical incision is made in the mucous membrane of the vestibule around the meatus, and about one-sixth of an inch distant from it. By means of fine scissors this incision is deepened, and the entire lower end of the urethra, for about one-third of an inch of its extent, is separated from the surrounding tissues. The piece of the urethral canal thus isolated is gently drawn down and removed by a snip of the scissors. The edge of the divided urethral mucous membrane may then be united to the edge of the divided vestibular mucous membrane by a few sutures, or the raw surface may be allowed to granulate. Cicatricial stricture may be prevented by the regular passage of a soft bougie. If a stricture should form, it may be easily remedied by slitting the urethra up for about a third of an inch. The prognosis as to the likelihood of recurrence after removal should be guarded.—*Univ. Med. Mag.*

TETANY IN MENSTRUATION, PREGNANCY AND LACTATION.

Dr. von Jaksch (*Wien. med. Presse*, 1891, No. 23) noticed the characteristic spasms of tetany in a woman, aged thirty-five, during the fifth month of pregnancy. She first noticed tetany, before a menstrual period, when nineteen years old. The symptom subsided and did not reappear till eighteen months later, during her first pregnancy. The second and third pregnancies were free from tetany, which reappeared during the fourth, and also the fifth, when she was under observation. This case was essentially chronic and seemed to arise from some disturbance associated with extirpation of strumous glands, dyspepsia, pregnancy and lactation. According to Professor Schauta, only a few cases of tetany in direct association with pregnancy have been recorded. Meinert, of Dresden, collected nine such cases in 1885. In one of these tetany

appeared in the third and sixth pregnancies, at an interval of eight years. The symptom increased towards the end of pregnancy, and ceased after delivery. Müller, of Berne, records a very instructive case. A patient, aged forty-five, suffered from tetany from the age of ten upwards, the attacks increasing greatly during her only pregnancy. Trousseau has seen forty cases of tetany during lactation, and about as many instances of this curious affection have been observed during menstruation.—*Brit. Med. Jour.*

PROPHYLAXIS OF PUERPERAL FEVER

J. Veit (*Berlin. Klin. Wochensch.*, 11th May, 1891) contributes an important paper on this subject, advocating almost complete abstinence from internal examination in attendance on labor. The external examination yields the position of the fundus, of the child and of the head, the condition of the child, of the mother, and of the membranes; and if these are all normal, no internal examination is necessary. The indications for internal examination in the first period of labor are—(1) General disturbances—*e. g.*, eclampsia, nephritis, fever, etc.; (2) Local disturbances—*e. g.*, discharge of blood, abnormal painfulness of labor or long duration; (3) Departure from the normal in external examination—*e. g.*, position of head above pelvis in primiparæ or after escape of waters in multiparæ, abnormal distension of lower uterine segment, slowing of fœtal heart sounds, etc. In the second stage of labor internal examination is only rarely indicated, and really only when the question of operative aid arises. In the third stage internal examination should only be made when there is excessive hæmorrhage, and in the puerperium only in fever or hæmorrhage.

AN EARLY SYMPTOM OF WHOOPING-COUGH.

Dr. Huguin, of Tourteron, affirms (*Union Méd. du Nord-Est*, May, 1891) that photophobia with dilatation of the pupil is a useful diagnostic symptom of whooping-cough in the early stage, before the cough has become characteristic. He cites three cases in support of this opinion; two of the patients were children and one an adult, and in all of them the symptoms referred to preceded any other manifestation of the disease.—*Brit. Med. Jour.*

PÆDIATRICS.

BACTERIOLOGICAL RESEARCHES UPON THE SALIVA OF CHILDREN SUFFERING FROM MEASLES.

The investigation of Mery and Pierre Boulloche lead them to conclude that the pneumococcus and the streptococcus are to be found in the saliva of children suffering with measles, with greater frequency than in healthy children. Broncho-pulmonary accidents rarely appear in connection with measles except in those cases in which the streptococcus or pneumococcus is to be found in the saliva. After death one may trace the pathogenic microbe which has been found in the saliva in the upper air passages as far as the smaller bronchi. The very frequent presence of the pathogenic agents of broncho-pneumonia in the saliva of children suffering with measles appears to explain the great number of broncho-pulmonary complications with that disease. Hence the necessity of the most vigorous antisepsis of the buccal cavity during the progress of the disease.

INTUBATION IN 1890–91.

A year ago Professor Von Ranke published statistics of 413 cases of intubation, collected from German, Austrian, and Swiss (German) sources, and compared them with 866 tracheotomies collected from the same sources, and performed within recent years. He now reports (*Münchener medicinische Wochenschrift*, October 6, 1891) 365 cases of intubation performed for diphtheritic croup in Germany, Austria, and Switzerland during the past year. Of these cases 94 were his own and the remainder were performed by the six following operators, namely, Ganghofner, Jakubowski, Von Muralt, Unterholzner, Schwalbe, Baginsky, and Escherich. He has also presented for comparison 237 cases of tracheotomy performed during the same period by Jakubowski, Steffen, and Unterholzner. Of the 365 cases of intubation 348 were performed for primary diphtheria, and 17 for diphtheria secondary to measles. Of the former 143 recovered, or 41 per cent., and of the latter 5 recovered, or 29.4 per cent. Among the whole 365 cases, therefore, there was 148 recoveries, or 40.5 per cent. It must be stated, however, that tracheotomy was performed

in 83 cases, or in nearly a fourth of the whole number, after intubation had been tried. Of these 6 eventually recovered, and it is not quite accurate to include these among the recoveries obtained by intubation, as Von Ranke appears to have done. Of the 237 cases of tracheotomy which he collected, 78 recovered, or 32.8 per cent. The results of intubation are, therefore, superior to tracheotomy, so far as these statistics are concerned, and there is a decided improvement in the results of intubation over those shown in Von Ranke's former report. On that occasion the recoveries from intubation were 34 per cent., and from tracheotomy 38.1 per cent., so that the relative position of the two operations is now reversed. The author attributes the better results to the greater experience which operators now possess, and to the improved tubes which are now employed. He attributes his own improved results in no small degree to the fact that he now leaves the thread in place, and has recourse to the extractor for removal of the tube only in exceptional cases. He thinks it a great advantage that, with the thread in place, the nurse is able to remove the tube when there are signs of its being blocked, and he has noticed that after its removal in such cases more or less membrane is often expelled, and the breathing is easier for a time. He lays stress on the fact that ulceration from pressure of the tube is now very rarely found, and this he believes to be due to the employment of properly constructed tubes.—*Brit. Med. Jour.*

HYGIENE.

THE DIETETIC VALUE OF PEPTONES.

In the current number of the *Journal de Pharmacie* of Antwerp, M. Denaeyer describes a very simple method for the determination of the dietetic value of peptones. The complete analysis is tedious and difficult, and it is even now by no means perfect. M. Denaeyer himself has done much towards its improvement, and we are not the less grateful to him for giving us a method by which the comparative merits of different commercial samples can be obtained with simplicity and some approximation to accuracy. The method depends on the fact that the more valuable constituents of a peptonic fluid are precipitated by strong alcohol, To this class belong albumen, albumose, peptone, and one variety of gelatine. The alcoholic extract retains in solution definite compounds such as creatine, tyrosine, and urea. The mode of working is as follows: 10 cc. of a 20 per cent. solution of peptone are treated with 100 cc. of strong alcohol; after standing for twenty-four hours the extract is removed by decantation, and the precipitate and extract are separately evaporated to dryness, the latter at 105°C., and each is carried to constant weight. The dietetic value of the peptone depends on the percentage of the precipitate, which contains all the true food constituents. M. Denaeyer states that the extract should not amount to more than 30 per cent. of the whole dry matter, any larger proportion being due to products of metamorphosis—such as leucine, tyrosine, aspartic acid, glycocol, amido-butyric acid, and the like. Such an assay, although of practical utility, cannot supersede complete analysis. It is evident, for example, that gelatin would be reckoned by the above process along with the valuable peptone constituents, since strong alcohol precipitates this body.—*Lancet.*

TO DISTINGUISH MARGARIN FROM BUTTER WHEN THE TWO ARE MINGLED.

"Alimentary fats," says M. Lezé, in the *Répertoire de Pharmacie*, "usually contain from 10 to 12 per cent. of water, and, therefore, in searching for a substance to free from this element, it is necessary to utilize something that has a great avidity for the same, without any affinity for the fat."

Syrup of sugar is his choice as an agent in this respect. A solution of sufficient density renders easy the separation of the two substances. He pours into a test tube of 10 ccm. capacity 1 or 2 ccm. of simple syrup, places the tube in a water bath, and adds, little by little, the butter to be assayed, until the 10 ccm. mark is reached. The tube is then corked and shaken, and then a strong thread is passed around the mouth and the tube is rapidly whirled around the head for several seconds. When the whirling stops, if the butter is pure, the fatty matter is clear and limpid, and the whitish emulsion of residual milk, water, and syrup is voluminous and well marked. If margarin be present, the fatty matter remains turbid and milky.

This process permits of the detection of 20, or even 15, per cent. of adulteration.

The aspect of the melted fats is characteristic, and, more than this, margarin exhibits normally the phenomenon known as super-fusion, and communicates this property to fats with which it is mingled. Thus we see a pure butter in cooling becomes first turbid, and finally becoming pasty, while butter, even with only a small amount of margarin, always preserves a semi-transparent condition.

MEDICAL CHEMISTRY.

TO OBTAIN PURE OXYGEN RAPIDLY.

Zinno's method consists in mixing intimately 200 gm. of powdered potassium permanganate with an equal weight of barium binoxide. On the addition of water, oxygen is disengaged. With the amount stated, at ordinary temperature, 13,620 ccm. of pure oxygen are generated. The oxygen is rapidly produced, and is not contaminated by chlorine or chlorine products.

BROMOL.

Bromol, which was introduced into therapeutics by Dr. Rademaker, is a chemical compound, tribromophenol, and is obtained as a white flocculent and gradually crystalline sediment when bromine water is added to an aqueous solution of carbolic acid. Pure tribromophenol occurs as a white crystalline substance which melts at a temperature of 203° F., and is nearly insoluble in water, but readily so in alcohol, ether, chloroform, glycerine, and in fatty and ethereal oils; the odor is disagreeable, like that of bromine; the taste is sweet and astringent. According to some experiments previously published by Grimm, the antiseptic virtues of bromol would seem to rival those of carbolic acid. When it is applied to recent wounds it causes a sensation of burning and has a caustic action; it stimulates atonic granulations, and produces a favorable effect on tuberculous processes. In gangrene it acts as a powerful disinfectant, and accelerates the separation of dead matter. Dr. Grimm applied it to wounds either in a pure state or mixed with some indifferent powder, and as an ointment. He also employed it to impregnate bandages. He considered it inapplicable to the mucous membrane of the mouth, nose, and pharynx. on account of its caustic properties. Dr. Rademaker uses bromol either in substance or in solution of olive oil of the strength of 1 in 30, or as an ointment of the strength of 1 in 10. In diphtheria he brushes the membrane with a glycerine solution of the strength of 1 in 25. As tribromophenol remains undissolved by the gastric juice and is only slowly acted upon during its passage through the intestinal canal, Dr. Grimm made use of it as a disinfectant of the bowel, giving it in doses of from three to seven and a half grains per diem. Dr. Rademaker also has adminstered it in cholera infantum in doses of from five to fifteen milligrammes, and has prescribed it in typhoid fever. It is secreted by the kidneys in the form of tribromophenol-sulphonic acid.—*Lancet.*

ALKALOIDAL ASSAY OF NARCOTIC PLANTS.

Dr. O. Schweissinger has has occasion to investigate the alkaloidal yield of narcotic plants cultivated near Berlin. He reports on his results in *Pharm. Centralhalle* (No. 41). The method of assay which he used was the following:

Ten grammes of finely cut dry herb (aconite, belladonna, etc.) are put into a flask, digested (warm) over night with 209 c.c. of water containing 1 c.c. of diluted sulphuric acid, the mixture being occasionally agitated. Flask and contents having been weighed as soon as the latter had been introduced, any loss of weight which the apparatus has suffered during standing is made good by adding enough water to restore the original weight. The mixture is then allowed to cool, strained, the residue pressed, and the strained liquid measured. It will measure, say, 180 c.c. (which would correspond to 9 gm. of herb). This amount is now evaporated on the water bath under constant stirring, during which time the temperature is conveniently kept at 65° C. (149° F.). When the residue weighs about 20 gm. the thin fluid extract is poured into a measuring cylinder or flask of the capacity of 100 c.c., and alcohol then added up to the mark (100), which causes precipitation. The whole is then thoroughly shaken. (Without this precipitation by alcohol the subsequent treatment with chloroform or ether-chloroform, by

shaking with these menstrua, becomes impossible, owing to the formation of emulsions.)

The evaporation may also be continued down to about 10 c.c., and alcohol then added to 50 c.c. In this case, however, the sediment settles much slower and filtration is more difficult.

After the sediment has been deposited the liquid is filtered. A measured portion of the filtrate is evaporated to 10 c.c., transferred to a separatory funnel, 1 c.c. of ammonia water added, and shaken with 40 c.c. of ether-chloroform (15 c.c. of chloroform+25 c.c. of ether). Twenty cubic centimeters of the ether-chloroform solution are then removed, evaporated in a capsule, and triturated with one-hundredth normal acid.

This method had been published by the author before, but since it has given him so uniform and accurate results, he has now republished it.

The results obtained by the author are interesting also to us, since they show the average yield of alkaloid under several conditions.

PREVENTABLE BLINDNESS.

Dr. C. D. Conkey, in an article in the *Northwestern Lancet*, on "Preventable Blindness," April 15, 1891, ably condenses much information in this compend, viz.:

1. The largest proportion of blindness in the young can be prevented.

2. The majority of cases of blindness develop in the practice of the general practitioner, in the course of the invasion of the grave diseases of childhood, or as a consequence to these, or as a result of a contagious leucorrhœa in the mother.

3. To successfully prevent them, prophylactic measures should be adopted in all cases where danger is suspected, or where the eye shows a tendency toward inflammatory action.

4. The physician should be sufficiently acquainted with eye diseases to treat them skilfully when the eye becomes invaded.

5. After all severe attacks of the diseases of childhood the patient's sight should be carefully tested before he is dismissed as convalescent.

NEWS AND MISCELLANY.

ANOTHER BOGUS AMERICAN DIPLOMA.

Recent numbers of American contemporaries announce the arrest of a Dr. (?) Van Vleck on a charge of issuing bogus medical diplomas, his institution going under the name of "The Medical University of Ohio," a title which is dangerously like that of The Medical College of Ohio, which, we are assured, is a comparatively reputable institution. Unfortunately the state of public opinion in far-away Ohio is not favorable to the repression of adventurers of this sort, and the lay press is strongly in their favor, on account of the advertisements which the quacks are shrewd enough to deal round with a liberality bordering on profusion.—*Med. Press.*

WORSHIPPING MEDICINE BOTTLES IN BURMAH.

A good story is told by the *Modern Church*. An eminent lady missionary in Burmah recently gave Dr. A. J. Gordon an instructive but somewhat startling chapter from her experience. In one of her tours, she said, she came upon a village where cholera was raging. Having with her a quantity of a famous pain-killer, she went from house to house administering the remedy to the invalids, and left a number of bottles to be used after she had gone. Returning to the village some months after, the missionary was met by the head man of the community, who cheered and delighted her by this intelligence: "Teacher, we have come over to your side; the medicine did us so much good that we have accepted your God." Overjoyed at this news, she was conducted to the house of her informant, who, opening a room, showed her the pain-killer bottles solemnly arranged in a row upon the shelf, and before them the whole company immediately prostrated themselves in worship.—*Rural and Colonial Druggist.*

INFLUENZA ABROAD.

A noteworthy difference between the present outbreak of influenza and those experienced last spring and the original epidemic of the winter of 1889–90 is the comparative slowness of its diffusion over the country. It is mainly confined to two widely separated parts of the kingdom—viz., Cornwall and the eastern counties of Scotland. The reports from the latter show that some towns and villages in Forfarshire, Perthshire, Fifeshire and Kincardineshire have suffered severely. In Dundee, the epidemic is on the decline, as also at Arbroath, where it has been particularly severe. At Lochee it is reckoned that more than 1600 cases have occurred during the past month, and twelve deaths are attributed to it. It has been very prevalent at Edinburgh, but it seems only to have appeared at Aberdeen quite recently. It is remarkable that children are being attacked almost as much as adults. Abroad, it is reported to be very prevalent in St. Petersburg and Berlin, whilst at Hamburg last week it had reached "alarming proportions," and the weekly mortality of the city and its suburbs exceeded the average by 280. In France it is especially prevalent at Bordeaux, where many deaths among the aged have occurred. It has also, as will be seen from our correspondent's letter, appeared in Paris.—*Lancet.*

COMPRESSED MEDICINE TO BE USED HEREAFTER IN THE ARMY AND NAVY.

The army medical service is interested in a contract which was awarded at the War Department for a new system of carrying medical and surgical supplies for an army. Ever since the last Sioux campaign there has been a growing demand for a plan by which supplies needed by the surgeons could be placed in a more compact form than liquid, and carried with greater safety and economy. The result of the award is believed to be as near perfection as possible. In a small, light wooden chest, 23 inches long, 14½ inches wide, and 17¾ inches high, are sixty square bottles, containing as many different kinds of medicine, but in compressed tablet form, none of them being larger than an ordinary peppermint lozenge. One of these lozenges or tablets contains all the necessary ingredients of a liniment, and when dissolved in an ounce of distilled water its healing properties are the same as if it was in liquid shape and in a big glass jar. Some idea may be formed of the perfection to which the art of compression has been brought by the fact that, if the contents of this small brass-bound chest were liquefied and in their customary jars and bottles, they would occupy nearly one-half of the space of a regular freight-car. After all, however, fluid extracts and powders take up less space than compressed tablets.—*Med. Rec.*

DIPHTHERIA IN MILAN.

The Nemesis of bad water supply has of late been conspicuous in the Lombard capital. We have drawn attention to the severity of the typhoid fever visitation due to that cause. Now we have to refer to another hardly less severe—that of diphtheria. It is in the schools that this latter scourge has been most prevalent, and, as usual, we hear of its ravages long after its first appearance. It must have been in the spring that it began to assume an epidemic form, and it was at midsummer that it numbered most victims. In April the cases were 67; in May, 65; in June, 76. July witnessed a decline in the frequency of its attacks. There were 51 in that month, 52 in August, and 33 in September, when the schools were closed for the holidays; but in October the cases rose again to 45. During the present month the diminution in number has been maintained, and also, it is said, the gravity of the symptoms has perceptibly declined; but there is still diphtheria enough in the city to justify the most active vigilance on the part of the Ufficio Sanitario, and the utmost anxiety in all interested in school management—parents and masters alike. A correspondent tells us of an outbreak of the disease in the Via Palermo, where a much-frequented *scuola communale* is situated. Six cases are already reported in that quarter. Milan has spent much on public buildings, some of which are among the finest in Europe. We have lately seen proposals to replace the façade of her world-famous cathedral by a new one. But as long as her drinking water continues the prolific source of disease, we should think that improved sanitary works, including an aqueduct to put a sufficient supply of *acqua potabile* within the reach of all her citizens, ought to take precedence of all others.—*Lancet.*

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. E. R. SQUIBB, of Brooklyn, N. Y. "On the Medicinal Uses of Hydrogen Peroxide." *Gaillard's Medical Journal*, N. Y.

DR. ROBERT T. MORRIS, of New York. "The necessary Peroxide of Hydrogen." *Journal of the American Medical Association*, Chicago, Ill.

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

SURGICAL PYELITIS.

By G. FRANK LYDSTON, M. D.,
CHICAGO.

Professor of the Surgical Diseases of the Genito-urinary Organs and Syphilology in the Chicago College of Physicians and Surgeons.

Gentlemen :—The first case to which I will direct your attention is one of considerable interest. The gentleman is forty years of age, and has been under my care continuously for the last four years. He consulted me originally for a very tight and tortuous stricture in the bulbo-membranous region. This was entered with difficulty after several weeks' faithful endeavor. Dilatation to the size of thirty-two French was finally effected, and occasional dilatation has since kept the stricture in a most satisfactory condition. When I began treatment of the stricture he was considerably debilitated; his digestion was bad, and he was suffering from numerous reflex phenomena of a neuralgic character, referable especially to the vesical neck, rectum, lumbar region. He had run down considerably in flesh. At no time during the treatment of the stricture were any unpleasant results of the dilatation noticeable. It was necessary as a preliminary to treatment by dilatation to incise the meatus. About a year after the stricture had been thoroughly dilated, the patient contracted a heavy cold and developed a slight cystitis, with a moderate amount of renal congestion and some albuminuria. The renal symptoms disappeared, but the urine never cleared up completely, although irrigation and local antiseptic treatment of the bladder, in conjunction with the ordinary measures of internal treatment for controlling cystitis, were kept up continuously for a considerable time. Some months after the cystitis developed, treatment having meanwhile been stopped for a while, the gentleman brought me a sample of his urine, which had assumed an appearance which alarmed him, and which he claimed was getting perceptibly worse. On examination I found an abundance of pus and caudate pelvic epithelium. I satified myself that I had to deal with a case of pyelitis secondary to chronic inflammation of the bladder. The bladder symptoms, however, did not return, nor had they at any time been severe. The pus in the urine increased in quantity, but there were no subjective symptoms. I finally succeeded in clearing up the urine to a great extent, but it all times contained a considerable quantity of pus. Exacerbations have occurred from time to time, but there has been no coincident constitutional disturbance. At times the pus has been present in such amount that on standing fully two-thirds of the bulk has appeared to be composed of almost pure pus.

I hold in my hand a sample of the first urine which the patient passed this morning, and you will notice that it is perfectly opaque and exceedingly thick, presenting the characteristic greenish-yellow appearance of pyuria. You will observe there are no clots of mucus, but the pus is evenly disseminated throughout the fluid, and presents what might have been described as a "powdery appearance." If this be allowed to settle, it will be found that the supernatant fluid will not become clear. This is a peculiar feature of pyelitic urine, and serves in a measure to distinguish cases of pyelitis from pure cystitis. Under the microscope there will be found in this urine (and I will be pleased to have some of the students examine it for themselves) an abundance of pus corpuscles; and it is proper in this connection to say something in a general way regarding the presence of pus in the urine in various conditions.

Pus corpuscles occur in the urine in cases of various forms of chronic inflammation of

the genito-urinary tract. Under ordinary circumstances it is impossible to distinguish them microscopically from mucous or chyle corpuscles. According to Peyer,[1] single pus corpuscles occur in almost every urine, especially that of women. As a matter of fact, the corpuscles described by Peyer are mucous corpuscles. The clinical features of the case must be taken into consideration in the differentiation of pus and mucus, as the microscope alone will not serve to distingush them. Whenever the form of corpuscles presented by mucus and pus occur in large numbers in the urine, the presence of pus may be inferred. Pyuria is invariably an indication of acute or chronic inflammation of some portion of the genito-urinary system. The pus corpuscles are about double the size of blood corpuscles, are opaque, and finely granular, this granular appearance serving to conceal their nuclei which, however, become visible on the addition of acetic acid. The pus corpuscles may be notched in appearance as a consequence of the shrinking of the corpuscular membrane. When the urine is strongly ammoniacal, the pus corpuscles dissolve to a certain extent and coalesce into a mass, losing their form, so that the microscope develops only their nuclei. When urine containing pus is first voided, corpuscles may present under the microscope the peculiar ameboid movement of the leucocyte. We find in these cases—in cases of chronic inflammation of the genito-urinary tract—as a rule, more or less epithelium. Epithelium, however, is frequently in normal urine, being indicative under these circumstances of the same changes that occur in the stratum corneum of the skin, viz., the shedding of effete epithelium. This shedding of epithelium is not abundant under normal circumstances. In the presence of disease it is increased. We therefore find in cases in which there is an abundance of pus or mucopus an increased quantity of epithelium, the form of which depends upon the site of the diseased process.

In case of inflammation of the renal tubuli and urethra the epithelial cells are rounded. Epithelial cells from the vagina and bladder are of the pavement variety, often hexagonal in form, nucleated, and are not to be differentiated from each other. Caudate epithelial cells originate most often in the renal pelvis, this form of epithelium being sometimes spindle-shaped. It is the characteristic epithelium present in cases of pyelitis. In some instances of severe inflammation about the neck of the bladder, caudate epithelial cells are exfoliated. Thus Peyer describes a case in which a large quantity of caudate epithelial cells were found in the urine after cauterization of the deep urethra. The clinical history of the case and the other pathological features of the urine must be depended upon for the deferentiation of the caudate epithelium from the vesical neck and that from the pelvis of the kidney. Pyelitis does not give rise to conditions of the urine which are absolutely pathognomonic of their origin, particularly if, as is frequently the case, vesical inflammation co-exists either as a secondary or primary condition. As is often seen, inflammation of the bladder may, by simple extension, result in pyelitis; while, on the other hand, the irritating product of inflammation of the pelvis of the kidney may induce secondarily vesical inflammation. There is a form of pyelitis resembling simple chronic catarrh of the bladder—and associated frequently with the latter—which frequently occurs in gouty patients, in whom a sensation of uneasiness in the region of the kidneys in combination with the appearance of more or less muco-pus, and the characteristic caudate cells of the renal pelvis in the urine enable us to diagnose the case with some positiveness. In such cases, however, if the neck of the bladder becomes implicated in the inflammation, the presence of caudate cells loses its significance. In a general way, we may state that we have in pyelitis, pus, blood and epithelium in the urine, the characters varying with the acuteness, duration and cause of the inflammation.

As I have already remarked, the pus is inclined to be of a powdery consistency and more finely disseminated throughout the urine than is the case in chronic vesical inflammation. It is, moreover, apt to be of a greenish color from the admixture of hæmatin. I have recently seen a case in which an exacerbation of pyelitis occurred in a young man who had suffered from stricture and vesical catarrh during the progress of malarial fever. In this case the urine had a most peculiar greenish hue, very similar to what might have been expected from the admixture of vegetable matter.

It is unfortunate that these special features of pyelitic urine frequently lose so much of their significance from the frequent co-existence of vesical complications. It must be remembered that abscesses in the vicinity of, and discharging into, the genito-urinary tract give rise to pyuria. In such cases the profuseness and possible intermittency of the purulent deposit in the urine and it close resemblance to the pus discharged from

1. Clinical Microscopy, Page 54.

abscesses in other situations, should lead to a suspicion of the condition present. Even in cases in which the marked clinical features of the case serve as a guide to the correct diagnosis of abscess, the source of the pus is overlooked. Thus I have recently had a case in which I operated successfully for an abscess secondary to disease of the hip-joint, which had discharged into the bladder, the cause of the pus appearing in the urine in this case having been overlooked by several competent surgeons.

A case was recently referred to me of a woman who suffered from chronic inflammation of the bladder with a discharge of an immense quantity of pus in urine. This case upon investigation proved to be one of pelvic inflammation with consequent abscess which had opened into the bladder. Cases of this kind must be taken into consideration in estimating the source of the pus in pyuria. During the progress of the case under consideration, there have been at various times, during the periods of transient renal congestion, mucous and granular casts in the urine.

There has been until recently an abundance of caudate epithelium. I think it will be found, however, that in the specimen which I present to you this morning, no pelvic epithelium will be found and no casts. The renal structure proper is apparently in very good condition, but the pelvic epithelium has probably been so extensively destroyed that its absence from the urine at this time is very readily explained. Considering the quantity of pus in the urine it might naturally be expected that this patient would be quite a sick man, but, strange to say, until within the past week he has not only been able to attend to his business, but has had a fair appetite, no pain or constitutional symptoms, and has received very little sympathy from his friends on this account. For the past week, however, he has been running down, his appetite has failed, diarrhœa and night sweats have come on, and as he has expressed it, he has "suddenly gone all to pieces." I might state, that he has been treated in every conceivable way within the limits of rational therapeutics, and with only moderate success during the several years that he has been under my observation. I am going to try in this case the effect of hypodermatic injections of chloride of gold and sodium.

I shall give for the night sweats Dover's Powder in five grain doses, with every expectation of success from its administration. I shall continue the administration of quinine and iron and cod liver oil, and shall put the paitent upon three milk punches per diem.

Subsequent Course of Case.—Gentlemen, you will recall the case of a patient with pyelitis whom I presented to you six weeks since, and to whom I informed you that I was going to administer the chloride of gold and sodium hypodermatically. The progress of the case has been most satisfactory, and as an evidence of it I present to-day a sample of this morning's urine. You will notice that it is almost clear. If allowed to settle it will be found that there is a very thin layer of purulent deposit on the bottom of the bottle. The patient is getting very fat; his pyuria is checked, and his night sweats have yielded to the use of the Dover's Powder. I might remark in this connection that you will find the Dover's Powder to be the most reliable remedy at our command for colliquative sweating, no matter what its origin may be.

I experimented quite extensively while an interne in the New York Charity Hospital upon the abundant clinical material in our medical wards to determine the relative value of the various remedies recommended for night sweats, particularly in pulmonary consumption. I found atropine not only unreliable but productive of certain disagreeable effects that more than counterbalanced its possible advantages. The mineral acids and other tonic remedies and astringent baths were not much more efficacious than the atropine, although, perhaps, not so objectionable in some directions. I established, to my own satisfaction, the fact that there are but two remedies which can be relied upon to check night sweats. These are the Dover's Powder and the active principle of cocculus indicus or picrotoxin, the former being by far the more valuable of the two.

With regard to the improvement in this case, I am satisfied that the administration of both chloride of gold and sodium hypodermatically is entitled to credit. I rather hesitate in making an arbitrary statement regarding the efficacy of this drug, particularly as its administration is just now quite a fad. But certainly in this case its use has appeared to be attended by most excellent results. How the treatment has acted I do not pretend to say, nor do I claim a single case proves such. I do desire, however, to call your attention to the case particularly, and shall take the opportunity of reporting it for what it is worth, in the hope that the remedy may be duly tried in similar conditions by other practitioners. It is but just to say that I have been using the drug for a

few weeks in several other cases of a milder type of inflammation of the genito-urinary tract, without having obtained as yet an appreciable effect. That the remedy has been in this particular case of valuable service as a tonic and alterative, and that it has had a special action on the affected structures is, to me, quite apparent. I do not, however, claim to entirely eliminate the possible element of coincidence in this solitary case. Further than what I have stated I do not pretend to explain the action of the drug.

I will not at this time expatiate upon calculous, tubercular and other forms of surgical pyelitis, with their attendant features of pyo-nephrosis, changes in the renal tissue, characteristic of the various forms of so-called surgical kidney perinephritic abscess, etc., but will reserve these topics for future consideration.

COMBINED CARDIAC LESIONS.

By JAMES M. ANDERS, M. D.,
Professor of Theory and Practice of Medicine, Clinical Medicine, and Hygiene at the Medico-Chirurgical College of Philadelphia.

Gentlemen:—I am anxious to call your attention to a case illustrating conditions that the books do not have much to say about, namely: combined forms of cardiac disease.

In most text-books on the practice of medicine, you will find very little said upon combined forms of heart disease, and in a great many of the best works there is nothing whatever on the subject.

Now, we know that in a great many cases of aortic valvular diseases, for instance, we have mitral diseases following. Let us bear that in mind. We know that in a great many cases of mitral disease we have, later on, incompetence in the right side of the heart, of the tricuspid valve, and in other cases disease of the mitral valve co-exists with or precedes the disease of the aortic valve, the one condition entirely independent of the other. So we ask, What influence has the disease at one valve upon the progress of the disease at the other and upon the symptoms of that disease? These are questions of vital importance.

When you have combined forms of heart disease you will, as a rule, notice that the lesion at one of the valves stands out quite prominently as compared with the physical signs or the lesions of other valves. Sometimes, however, you will have the trouble at one valve manifesting itself quite as well as at the other, and in these cases you will have frequently great difficulty in making a correct diagnosis and in giving a rational prognosis. Bear in mind that you will meet with them in practice, and that they will give you much more trouble than cases of simple valvular lesion.

We find that the woman before us, H. R., age 25 years, is married, has had three children, and no miscarriages. Father is dead, mother is well except for an occasional cold. The patient has always suffered with sore throat on taking cold. Five years ago she had her tonsils cut, after which the throat improved. A year later she had an attack of suppurative quinsy. Abut a year after she was attacked with a feeling of fulness in the median line of the thorax. This is still present and seems to start from the stomach and result in severe pain, which frequently extends to the forehead and right arm. The pain occasionally causes nausea and vomiting, which has occurred from twice a week to once in two weeks. The pain is especially severe at night, having caused her to rise from bed two or more times every night for the last three years. There is no specific history: appetite is capricious, bowels costive, tongue clean.

You may remember that on making a physical exploration of this chest we found several heart murmurs. We found what we thought was a presystolic murmur at the apex, a systolic murmur at the same place, a systolic murmur at the base, and a diastolic murmur also at the base, making four murmurs. Bear in mind what I said a moment ago about the lesions of one valve standing out prominently. So we find here that the murmurs and the symptoms which corroborate aortic disease seem to predominate over those at the mitral valve. We have here a loud, harsh murmur, heard over the second inter-space to the right of the sternum. We find it transmitted very clearly through the carotids. We find it, however, present over the whole upper portion of the sternum. The fact that you hear it over the whole upper portion of the sternum does not mean that it is not due to aortic stenosis—it is aortic stenosis. But that murmur which is heard all over the upper part of the chest, and is systolic in rhythm, must, if it is due to aortic stenosis, be heard in the carotids, and this is the case here. We also heard a murmur with the second sound, a post-systolic or diastolic murmur in the same situation. It is

almost continuous with the sound we heard that is systolic; was shorter in duration and much less marked, but being diastolic in rhythm, it must be due to regurgitation at the aortic valve. It is made by the recoil of the aorta causing the blood to flow back into the left ventricle.

An interesting point about cases of this kind is this: You have a double murmur at the aorta. Which lesion predominates, the stenotic or regurgitant? Bear in mind, you may have extensive regurgitation and yet have but a feeble regurgitant murmur. You listen over the carotid artery, and if you find that with the first sound you have a strong murmur—a strong aortic stenotic murmur—and a comparatively feeble regurgitant murmur in the same situation, as in the case before us, you are justified in saying that stenosis predominates over regurgitation. If, on the other hand, you find a murmur that is about as well marked during diastole as systole, or if you hear a diastolic murmur distinctly over the carotid artery, and that murmur is preceded by a systolic murmur, then you are justified in believing that the regurgitant predominates over the stenotic lesion.

So in this case we have well marked murmurs over the aortic valves, but we also have a systolic and presystolic murmur at the apex. Bear in mind that from extension of inflammation we may have aortic disease, leading to mitral disease, or the blood pressure of aortic regurgitation may lead to mitral incompetency. In this case the aortic lesion seems to predominate (the aortic stenotic murmur predominating over the aortic regurgitant), and as a natural consequence the mitral trouble following the aortic. In other words, we had aortic stenosis, then regurgitation, the condition leading to mitral regurgitation, and finally stenosis.

Not often do books speak of mitral stenosis, following regurgitation but I have found it so, although the reverse is more often the case. At all events, we have four distinct murmurs. Can you make out four distinct lesions in such cases? Certainly. You cannot rely in these cases upon the symptoms, nor upon the changes that have been produced in the cardiac muscle. For instance, if you have mitral stenosis by itself you have not enlargement of the left ventricle, but rather the reverse, a feeble impulse beat because less blood gets into the ventricle, and you have an anæmic appearance because less blood reaches the peripheral circulation.

You have that same lesion occurring with aortic regurgitation. The blood flows back into the left ventricle, and this, together with the current from the auricle, causes the ventricle to dilate on account of the increased amount of blood flowing into it; and to hypertrophy from the increased work. Hence it is that in all these cases we have a hypertrophied as well as a dilated ventricle. You would not look for a small left ventricle simply because you have stenosis in this case. So you cannot rely upon the changes produced in the cardiac muscle where you have combined forms of heart trouble. You cannot rely upon the subjective symptoms because the symptoms of one trouble simulate those of others in heart diseases, and because they are modified by two or three different lesions. The one thing you can rely upon is the seat of maximum intensity of the murmurs, their rhythm and area of diffusion. In everyinstance here you can confirm the diagnosis by listening to the murmur.

I would like to tell you something about the influence of disease of the aortic valve, upon disease of the mitral valve, tell you something as to how disease of the aortic valve modifies the prognosis and treatment of mitral valvular disease, and other subjects that are of interest and importance to you, and that are hardly touched upon in the text books, but time will not permit.

We, at first, gave this girl for her double lesion digitalis, which seemed to distress her more. I ordered her this because she had œdema and evidences of broken compensation. To-day we find she has not œdema of the feet. Compensation remaining unbroken there is no reason for increasing the force of the contraction of the left ventricle. We have, therefore, taken her off digitalis and are now giving her iron, with the idea of feeding her heart muscle as much as possible, and additionally are treating the catarrhal condition of her stomach. That catarrhal state was due to trouble at the mitral value. She has not vomited since she was last here, the stomach being in much better condition, while all the other symptoms are much improved.

TESTING CASTOR OIL.

To detect cotton-seed oil in castor oil, 10 grams of the suspected oil are mixed with 6 grams of a reagent made with 5 grams nitrate silver, 1 gram nitric acid, 100 grams alcohol, heated to 100° C. on water bath. In presence of cotton-seed oil the mixture assumes a red color after five minutes.—*Apoth. Ztg.*

COMMUNICATIONS.

PATHOLOGICAL CONDITIONS OF NOSE AND THROAT AS CAUSAL FACTORS IN ASTHMA, WITH A REPORT OF SUCCESSFUL CURES OF ASTHMA.*

By LOUIS E. BLAIR, M. D,
ALBANY, N. Y.

As the title indicates, it is not the purpose of this paper to discuss at length all the various ideas which have at different times been advanced by the many writers on the subject of asthma, or to review the several theories which have been faithfully followed for a time, and then discarded for others no more satisfactory in their results. What interests us directly is: How far do abnormal conditions of the nose and throat cause or modify asthma; and in what relation do the corrections of these pathological conditions contribute to a cure?

I think a new landmark in this subject was established when Weber, in 1872, disputed the bronchial muscular spasm theory of all previous writers. Salter, however, in his extensive researches believed that asthma was essentially a neurosis, and this effect was directly exerted on the cells of unstriped muscular fibre in the bronchial tubes, causing a spasmodic contraction of the same. If we consult the highest authorities, such, for example, as Duane's Dictionary of Medicine, Reynold's System of Medicine, and Pepper's System of Medicine, we find a definition of asthma which is quite vague, while nothing is said for its pathology or even surmised as to its real cause. They have all essentially followed Salter, but none explain satisfactorily the moist second stage, which seems to be due to something else besides muscular spasm solely.

Theodore Weber advanced the theory that the cause of the paroxysm lay in the paresis of the vasomotor nerves presiding over the vessels of the bronchial mucous membrane. He claimed "that under the influence of this vasomotor paralysis there occurs, from some cause, a sudden letting up of the control which is exercised over the calibre of the blood vessels, whereby they become distended to such an extent as markedly to interfere with the passage of air through the bronchial tubes. This paralytic condition having lasted a certain length of time, the membrane maintaining a dry condition, as is always the case in the first stage of the inflammatory processes, gives way and there follows an escape of serum and sero-mucus, thus relieving the engorged blood vessels, which soon regain their normal calibre, coincident with the cessation of the paroxysm." This theory, says an eminent writer, completely harmonizes, not only with the clinical history of asthma, but with the clinical history of the paroxysm. It also favors the nervous cause.

Weber could not assign clearly the disturbing causes which set up this irritation and prolonged it so as to modify the functions of the puenmogastric nerve; however, his paper set other observers to thinking.

A purpose of this article will be to show how the vasomotor nerve supply in the bronchial tubes is naturally disturbed by seemingly remote causes, and by virtue of the anatomical relations which exist in the upper air passages. Let us look then, in passing, at the relations of the mucous membrane and nerve supply of the nose and throat to the lungs, and notice how it is reasonable to suppose that disturbances here can remotely produce such serious paroxysms as are found in asthma and hay fever. This condition is a reflex neurotic one, which is clearly demonstrated by the systemic effects which sprays of cocaine have on the mucous surfaces of the nose and throat; and likewise the use of ether, chloroform, morphine, etc., in overcoming an attack. Dr. Jacobi stated in a recent discussion before the New York Academy of Medicine that "he had seen at least a dozen cases of chorea which had no other cause than chronic nasopharyngal catarrh, deviation of the septum, ozæna, hypertrophy of the tonsils, etc.;" and Dr. Baruch remarked: "The first positive case which removed my scepticism on the reflex influence of nasal peripheral irritation, is a cure of true epilepsy." He traced the cause, as he believed, in the nose, and by removing the cause he cured his patient.

The nerve supply in the nasal cavities, apart from the special nerve of sense, is derived almost entirely from the sphenopalatine ganglion (Meckel's ganglion), the largest of the cranial ganglia, and a part of the sympathetic nervous system. This ganglion also distributes branches to the throat, the head, and soft palate and eustachian tube. Connected with the three divisions of the fifth pair are the four small ganglia which form the cephalic portion of the sympathetic system. Meckel's ganglion is connected with the second division. All the four receive sensitive filaments from the fifth, and motor and sympathetic filaments

* Read before the Albany County Medical Society, Albany, N. Y., Dec. 30, 1891.

from various sources. The ganglia are also connected with each other and with the cervical portion of the sympathethic. Meckel's ganglion is by the videan nerve connected with the facial and the carotid plexus and the pneumogastric. From this anatomical description the sympathetic nervous relations which exist between the nose, throat, eye, ear, larynx, and bronchial tubes will readily be seen.—(Gray, Allen and McClelland.)

Van Loven proved experimentally that irritation of the sensory nerves is followed by reflex engorgement of the territory to which they are distributed. Sexton (The Ear and its Diseases, 1888, page 82) says this of the sympathy of the nerves: "In certain conditions of the system the nerves become exceedingly impressible to excitation. Thus, the irritation produced by the introduction of a speculum or a probe in the external auditory canal will excite coughing, or a desire to swallow and various other sensations in the nose, throat or larynx. Many persons can locate the seat of local irritation thus propagated in the ear in some particular spot in these parts, the sensation being described as burning, tickling, and the like. There is very often an increase in the secretion of mucus in the spot thus irritated. When nerve tension has been long disturbed in this way, reflex phenomena are easily excited; continuous aural, nasal, or dental irritation, even if imperceptible, may affect one part or another until nutritive (trophic) changes are brought about." Now what Sexton has said of the ear and its relations, the same may be said of the upper air passages and the bronchial tubes. Just as surely as a disturbance in the stomach will call forth an asthmatic attack in the proper subject, so also will a seemingly slight offence often, by dust, atmospheric conditions, or otherwise, have its weighty effect on the sympathetic nervous system, though the spheno-palatine ganglion and other nerve connections as instanced.

Bartholow, in discussing the pathology of hay fever, one form of asthma, has this anatomical explanation to offer: "The sneezing, the asthmatic symptoms, and other nervous phenomena, are purely reflex effects, readily explained by the anatomical relations of the affected nerves. Vulpian had long ago shown that ablation of the spheno-palatine ganglion, a centre of the sympathetic nervous system, was speedily followed by profuse catarrh of the nasal mucous membrane. The nucleus of the fifth nerve has close physiological relations with the nucleus of the pneumogastric nerve. Hence a reflex disturbance originating in the terminals of the fifth, may thus involve the terminals of the pneumogastric and its associated nervous conditions, causing amongst other nervous disturbances asthmatic symptoms."

Having noticed the anatomical relations and close sympathy existing in the nose, throat, and bronchial tubes, the results of the theories of Weber will now be taken up, and the further development briefly reviewed. Valtoline in the same year reported a case of asthma, which was promptly cured by the removal of nasal polypi, showing a sufficient cause from reflex nasal irritation. Hack, of Freiburg, Germany, shortly after claimed that there were certain definite "centres" of irritation capable of producing uniform reflex phenomena, such as occur in asthma, and suggested that the anterior extremity of the lower turbinate especially was the region which, in all asthmatics, ought to be removed. His radical theory was not accepted in full, but was productive of good in adding a new idea to further nasal investigations. Before Hack's valuable work appeared, Daly, of Pittsburg, read a paper before the Congress of the American Laryngological Association in New York, in 1881, upon the subject of hay asthma in its relation to nasal and neurotic factors. That paper seems to have been epoch-making in the study of this subject. He attributed the annual recurring attacks "to local chronic disease, upon which the exciting cause acts with effect," and among other things he said: "The parts should be put in order and thereby enable them to withstand the exciting influence of the next recurring crop of bacteria." To criticise Daly's views, with all due respect for his other valuable suggestions, as he was the first to call attention to the condition of the upper air passages, it might be said that his language is somewhat vague and indefinite when he speaks of bacteria as exciting influences. Bacteria have nothing to do with the case. His theory was, to a great extent, borne out in practice, and while he did not at that time fully comprehend the full significance of his new ideas, still he saw his cases do well. Just as soon as the nose and throat were put again into a normal condition the attacks of hay fever were relieved and, in many instances, cured. Daly, however, only thought that this treatment applied to a special kind of ailment, and he did not indicate anywhere that it had reference to asthma in general. Other writers soon elaborated his ideas, and Roe, of Rochester, was

the next to add "that hyperæsthesia is associated with, or occasioned by, a diseased condition, either latent or active, and that the removal of the diseased tissue in the nasal passages removes the susceptibility of the individual to future attacks of hay fever." In the same year Sajous wrote independently of Roe, and believed "that hay fever was due to an idiosynocrasy on the part of certain individuals to become affected by certain emanations;" that "organic alteration of the surface of the nasal mucous membrane altered its sensibility, and destroyed what morbid irritability might have attended the nervous filaments distributed over it," and also that "hypertrophies of the nasal mucous membrane increased its irritability and the intensity of the symptoms."

In 1884, McKenzie, of Baltimore, suggested the term "coryza vasomotoria periodica," on the ground that "the disease is essentially a coryza, showing, in most cases, a decided tendency to periodic recurrence, and dependent upon some functional derangement of the nerve centres as its predisposing cause, and for the production of a paroxysm, a certain excitability of the nasal cavernous tissue is necessary (brought on by a multitude of external irritating causes), plus a hyperæsthetic state of (probably) the vasomotor centres."

He, like the previous writers, had nothing to say for asthma in general, having only hay fever in his mind's eye.

Sir Andrew Clarke, in 1885, formulated his views as follows, which seem to comprehend the scattered opinions of others before him, and which, in a great measure, harmonizes them. According to his theory there is (1) A neurotic temperament (the views of Beard, Bleckley, and others); (2) a local condition of irritability, or positive pathological changes in the upper air passages (the views of Daly, Roe, Sajous, Allen, McKenzie), and (3) an external exciting cause.

Roe, of Rochester, in the *New York Medical Journal*, 1887, summarizes an article on hay fever, and among his conclusions he says: (1) That all cases of hay fever have their initiatory lesion in a diseased condition of the nasal fossæ; (2) that the disease of these tissues induces in the ganglionic centres connected with them an abnormal activity, which is reflected to other tissues and organs; (3) that the disease in the nose may produce disease in other portions of the respiratory tract, which may become independent centres of irritation; (4) that the affection is not *per se* a neurotic disease, nor necessarily associated with a nervous temperament, although persons having a highly nervous temperament, or a neurosis, are much more susceptible to the influence of a local irritant. Roe further says "that the neurotic condition which is often regarded as a cause of hay fever, is itself often developed as the result of the local irritation. These views differ widely, of course, from those held by Clarke and many others. Morrell McKenzie is more conservative. He says: "While admitting that many reflex phenomena may arise from disease within the nose, I must caution the younger specialist that the various complaints referred to as resulting from nasal disease are much more frequently due to other conditions, and that every other possible cause must be eliminated before the nose is incriminated."

Up to 1887 no writer endeavored to show that perennial asthma and hay asthma had anything in common. All the previous writers tried to solve the problem of hay fever, and had nothing to say for perennial asthma, for they saw no relationship between them. Bosworth made a further advance. He showed in an exhaustive and most valuable essay that, according to a vast clinical experience and painstaking observation, hay asthma and perennial asthma, as he classified the latter to distinguish it from the former, were, as he believed, but two subdivisions for the general term asthma. To hay asthma he gave the name vasomotor rhinitis, and to perennial asthma, vasomotor bronchitis. With reference to the existence of the intra-nasal disease, he found such to exist in every case, and to such an extent as to point conclusively to its strong causative influence in producing a paroxysm of asthma. He says such conclusions might easily be questioned, but thinks his argument is good when of the eighty cases he had, forty-six were cured, twenty-six were improved; and this was entirely due to the result of treatment of the nasal disorder. And he further reasons that, if the attack of asthma is cured by curing the nasal disorder, the asthma itself is *caused* by the nasal disorder. He also believes that the neurotic habit has also a great causal influence, and this nervous condition must not be lost sight of in the treatment. Bosworth further says: It is not yet an axiom that every individual of neurotic habit, who suffers from an obstructive lesion in the nose, will necessarily have asthma. However, he believes very often asthma is present in a mild degree, and a careful diagnosis not being made, the distressing symptoms are referred to a supposed

attack of bronchitis. And so the asthmatic habit is insidiously formed, and only when it is worse does it become manifest. In conclusion, he says, he believes three factors enter into the causation of asthma, viz., (1) A neurotic habit; (2) the nasal disorder; and (3) atmospheric conditions—the nasal disorder far outweighs in importance not only the nervous, but all other elements.

At least seven months before I saw Bosworth's article, I was treating perennial asthma in precisely the same way as this author, and as I had been treating hay fever, and reasoned from the close anatomical relation of the upper air passages to the bronchial tubes that the diseases were quite analogous and very likely but different manifestations in different individuals with certain modifying influences of heredity diathesis, etc. I desire to quote a few lines from a letter written to the father of a little patient I treated, who lived in Texas, and who was desirous of learning what I thought of his child's case and what my ideas were as to the plan of treatment, and what could be looked for. The history of this case will be given shortly. I explained to him briefly the close sympathy anatomically existing, and how all the symptoms in his boy's case clearly pointed to the nose and throat as being the seat of most of the trouble. These sentences occur in the letter: "By treating all diseased conditions found in the nose and throat and by building up his strength with suitable tonics, etc., in this way, I think, a great deal may be done for your boy. It appears to me to be by far the most promising plan of treatment yet suggested, as it aims to remove causes and sources of irritation." This patient was entirely cured of an asthma which he had since birth.

I think the fact which has not been properly brought out by previous writers is the *exposed position*, so to speak, of the sympathetic nervous system in the upper air passages through Meckle's ganglion and its numerous connections. All pathological conditions here, whether in the form of deflected septum, nasal spurs of bone causing contact, enchondromata, polypi, hypertrophic rhinitis, etc., may have a direct disburbing influence in causing asthma and hay fever, as has been fully shown. Various authors have queried about causes, and have hidden their indefinite explanations behind the terms "reflexes" and "reflex influences." Here, I believe, is a plausible anatomical reason clearly set forth, and it ought to be emphasized, that: Pathological conditions of the upper air passages have a causal relation in producing or influencing directly the lumen of the minute bronchial tubes causing the embarrassment in the respiratory function in the *first stage* of asthma, and the consequent catarrh in the *second stage*, so ingeniously claimed by Weber. So far as the vasomotor nerve centres are disturbed in the lungs it is easy enough to understand, by referring again to the anatomy of this system. Kirke's Physiology (Wood's Library, 1885, vol. 1, p. 254) says: "Experiments by Ludwig and others show the vasomotor fibres come primarily from the grey matter (vasomotor centre) in the medulla. Thence the vasomotor fibres pass down in the interior of the spinal cord, and issuing with the anterior roots of the spinal nerves, traverse the various ganglia on the prævertebral cord of the sympathetic and accompanied by branches from the ganglia pass to their distributions. These nerves have direct control in modifying the calibre of the blood vessels. An increase of the blood pressure may be produced, among other causes, by stimulation (irritation) of the vasomotor centres in the medulla reflexly by stimulation of the sensory nerves anywhere.

HISTORIES AND SUMMARY OF CASES.

This paper covers a period of observation of five years, and is based upon a study of the cases which have come under my notice. Most of these patients I have had under observation since, and have been familiar with the results of treatment; and have been able to verify the benefits which in most cases have been obtained. I have the record of more than thirty-five cases of asthma and hay fever, but desire to note the histories of only three or four which are typical ones, and illustrative of the pathological conditions found in the nose and throat of such cases, and the method of treatment which was pursued.

Case 1. Louis M——, aged 11. Residence, Galveston, Texas. Has been a great sufferer from perennial asthma and hay fever for years, his asthmatic difficulty dating from the time he was two months old. Has tried all sorts of medication and treatment, including change of residence, both at the seashore and in mountainous regions. His mother said, to her knowledge, he had seldom been an entire month free from some of the distressing symptoms of asthma. Being advised to try a Northern climate, as a last resort, she came to New York City and consulted Prof. Loomis. He gave her no encouragement after examining her child, but thought that inasmuch as she was North she might try a mountainous climate, and suggested the Catskills. She went there, and during the six weeks she was at

Palenville she said her boy never suffered worse, and was satisfied that it was not the place for him. She was very much discouraged, and was about to return to her home in Texas. Having relatives in Albany she paid them a visit before returning, and while here some one suggested my name favorably to her. She brought her boy to the office to see if any relief could be found for him. For days he had not been out of his clothing, his asthma being so bad that it was impossible for him to lie down. The dyspnœa was very urgent, and his whole countenance plainly told what a sufferer he had been. Upon making a careful examination of the nose and throat the following abnormal conditions were found: Both nasal fossæ were very nearly occluded, with enlargement of the middle and lower turbinated bodies, and pressing against the septum; the naso-pharynx was almost filled with adenoids; both tonsils were hypertrophied, almost meeting the uvula in the middle line; the uvula was elongated and rested constantly against the lingual tonsil, which was also very prominent. What was especially noticeable was the extreme sensitiveness of certain portions of the mucous membrane of the nasal passages, especially over the cartilaginous septum and bones; and if but lightly touched with a probe a severe coughing spell, with sneezing, would be called forth. Dust of any kind in the atmosphere would make him decidedly worse, and he had a perfect dread of being in or near a room where sweeping was done. He was troubled constantly with intense itching and burning in the nose, and the slightest cold in the head would make his asthma worse. He was busy fussing with and rubbing his nose almost constantly. In fact he seemed to be all nose. Physically, he was poorly developed, his chest was flattened and narrowed, as is characteristic of children suffering with adenoids of the nasopharynx and enlarged tonsils, both of which conditions rendering free breathing and hence perfect oxygenation impossible. His appetite was poor and his whole appearance denoted one of suffering. His weight was forty-seven pounds. I began to treat him September 1, 1889. The plan of treatment was to alter the hyperæsthetic condition of the mucous membrane in the nose; remove all abnormalities as far as possible; to correct the condition of things in the nasopharynx; to remove the tonsils, etc.

November 1.—Eight weeks after beginning treatment, I noted that his condition was considerably improved. The itching and burning in the nose, and tendency to cough and sneeze gone; can sleep flat on his back now, for the first time since he was an infant; appetite much better and has gained ten pounds in weight.

December 10.—Has no more asthma; eats and sleeps good, and has gained fourteen pounds.

February 15.—The favorable gain continues and has had no attacks of asthma.

He continued to improve very perceptibly, and during the next eighteen months had only one relapse of asthma, due to an attack of bronchitis, brought on by gross carelessness. He grew four inches in height and his weight was seventy-two pounds, a gain of twenty-five pounds. He was entirely cured of an asthma which he had, dating almost from his birth.

Case 2. John G——, 9 Delaware Street, æt. 21, occupation wheelwright and blacksmith. Has had asthma since he was five years old; has had many severe attacks lasting many days at a time. In the summer time has had frequent relapses of asthma, suggestive of hay fever, which would disappear again with the appearance of frost. His occupation as a blacksmith was very unfavorable for his nose and throat, and when the air was filled with dust he always suffered with a relapse of asthma. He was only able to work about one-third of the time. His attacks of asthma were so severe that there were many days consecutively that he could only find ease by sitting upright in a chair leaning on a pillow, resting his head on another chair in front of him.

Examinations of nose showed hypertrophic rhinitis, and the usual sensitive spots and areas which have been so well pointed out by McKenzie, Daly, Roe and others. Touching these sensitive places would at once set up a fit of sneezing and nasal coughing, and if persisted in would provoke a slight asthmatic attack. It was also interesting to note in connection with the treatment that after the use of the cautery or an acid in the nose, the reflex irritation would produce usually a severe relapse of asthma, lasting very often for two days, which very clearly pointed out nasal irritation and its reflex disturbance on the nerve supply in the lungs. This has often been observed in other cases, and I have often told patients not to be surprised if their asthma would be at times worse immediately after treatment, and wherever this reactive asthma has been marked the result of treatment has invariably been good.

Contrast with this the observation of R. H. Blaikie (Edinburgh) who says: "In the case of reflex neuroses, due to nasal affections, cocaine may be used to confirm the di-

agnosis, since the parts of the nasal passages to which it is applied will no longer be capable of producing the symptoms, such as fits of sneezing, asthma, etc., which their former condition set up.

I began to treat this patient December 1, and twenty days after made the following note in my case-book: No asthma except after cautery and has gained ten pounds.

March 1.—No more asthma since beginning treatment and has gained twenty pounds. Has not lost one hour from his work this winter by reason of sickness, something which he never did before. He was discharged cured. I saw him a year and a half afterward and he had gained eighty pounds in weight, and was a car builder at the West Albany shops. He considered himself physically as well and strong as any man in his shop, and had not lost a single day from work by reason of his former malady since he stopped treatment.

Case 3. Miss Mary K——, æt. 13, a patient kindly referred to me by Dr. Townsend. She was suffering with hay fever and perennial asthma, the latter, however, was quite mild, only showing itself when an acute attack of bronchitis would come on. She had been ailing with her asthmatic difficulty since her second year, and in her third summer had real hay fever. Her parents tried all sorts of medicines and cures, change of climate, etc., but all to no purpose. She suffered intensely from a constant itching and burning in the nostrils, which extended to the eyes, and the lids and surrounding tissues were actually ecchymosed from the severe rubbing and weeping, giving her face a very peculiar appearance. There was also a considerable conjunctivity, photophobia, etc., and together with the very sensitive condition of the nose, her feelings were anything but comfortable. Examination of the nose showed: Right side—septum anteriorly and low down an exostosis extending lengthwise backward, covered with a mucous membrane exceedingly sensitive and in close contact with the lower turbinate, which was abnormally large. The pressure here by contact was a constant source of irritation, and had a very decided influence in keeping up this difficulty. The whole septum was exquisitively tender, and touching it lightly with a probe anywhere caused severe pain, lachrymation, and set up at once a paroxysm of sneezing and coughing. The middle turbinate was likewise hypertrophied and tender. Left side—hypertrophic rhinitis is also marked, but the mucous surfaces not so sensitive. The method of treatment consisted in removing the exostosis, in separating the two sensitive surfaces from further contact, in obliterating the tender spots as far as could be determined; to place the nose and throat in a healthy condition, etc.

I began to treat her August 17, previous to which from June 1 she had been a great sufferer from all the usual and distressing symptoms. After the first treatment, which consisted in removing the exostosis from the septum, she had a severe relapse of asthma, and had others also due to the operation. Six weeks after the first visit all traces of hay fever and asthma were gone, and she has enjoyed unusually good health ever since.

Case 4. Bessie F——, aged 9, a patient kindly referred to me by Dr. Gorham. Had a history of asthma dating almost from her birth, and suffered very much like Case 1, Louis M——. The condition of the nose and throat was very much like that of the little boy, and her difficulty was a most obstinate one to relieve. After months of careful treatment her condition was but very little improved. Her general health was poor.

However, I felt confident that as her general health would improve, her asthmatic trouble would do better, and so predicted. There were many sources for reflex irritation removed, and judging from the success in the other cases, and taking into consideration her age, it was reasonable to infer that the old difficulty would be removed. Six months after I last saw her, I received a letter from her mother, saying that Bessie had never been so well, and was gaining constantly.

CONCLUSION.

I have thus dwelt at length upon the various theories and views of writers in order to show what the advanced sentiment is in regard to this subject in medicine, which evidently remains to be written. Its present treatment by therapeutic means alone is very unsatisfactory as every one will admit. Time-worn remedies have been discarded for newer ones more encouraging, and these in turn abandoned for others. There is no specific for asthma. Each case must be studied by itself. The physician must satisfy himself as to the *integrity of the upper air passages*, more especially the nasal cavities. Here is the most prolific cause of asthma, a fact which has now been fully proven by most careful writers, and by most successful and convincing records of treatment. In all of the thirty-five cases which I have treated, abnormalities of the nasal cavities were verified; and those cases which were not bene-

fited, I believe, that other and remote nervous disturbances were influential in keeping up a reflex asthma.

204 State St.

SPECIFIC FOR "LA GRIPPE."

By JOHN D. McGIRK, M. D.,
PHILIPSBURG, PA.

I wish to make a statement to the medical profession concerning my experience in the treatment of the prevailing epidemic, la grippe, or influenza, which is producing such a furor in the world, and in the treatment of which there seems to be nothing but confusion. The treatment of this disease, so far as a specific has been found, seems to have been given up by common consent. This was admitted a few days ago by one of our eminent professors in a lecture to his class, and was published in the Philadelphia Times of the 6th instant.

The number of remedies suggested has been very great, most of them useless, many unscientific, and some extremely foolish; such, for example, is the treatment with whisky and quinine—a more unlikely combination to cure a disease like la grippe could scarcely be conceived.

If this influenza is the same disease, and characterized by the same symptoms in Philipsburg, Pa., as it is everwhere else, and known by the common name of the "grip," then I claim that the treatment I have been using is a specific in the fullest meaning of that word. I claim that the remedies I use will completely and permanently break up the disease in from eight to sixteen hours in every typical case, which I have seen verified in more than two hundred cases of an unbroken record, and which I am now treating daily without a failure. The specific is a combination of fluid extract of aconite root and fluid extract of gelsemium. The aconite controls the fever, while we have in the gelsemium the most powerful febrifuge and anti-neuralgic remedy in the pharmacopœia, and in the combination of these two we have a therapeutic Hercules which, in power and range of application, cannot, apparently, be equaled by any other drugs in the world.

Now let us apply the treatment. I see my patient, say at 9 A. M., an adult of ordinary size and physique, and listen to the following history: "I felt chilly for several hours yesterday, then I began to have headache and pains all over my body, now I am burning up with fever and my head is almost bursting, and my eyes pushing out of my head. My head feels as if there was a force pump inside of it trying to break through the skull. I never had such a headache in all my life—what is it doctor? Is it what they call the 'grip'?"

The above is a fair sample of what every doctor has heard. I now examine my patient, and find a full bounding pulse (such as would indicate bleeding forty years ago) of from 100 to 140 pulsations to the minute; skin very hot, it may be moist, but is usually dry; temperature 102° to 105°; skin, red; face, flushed; eyes, red, prominent and full of tears; great thirst, and, perhaps, delirious, etc. This is the disease which has been prevailing in our town, and what we recognize as la grippe. I assure my patient of a speedy and permanent recovery. I take from my pocket case a vial of fluid extract of aconite root and put three drops in a glass, and add twelve drops of fluid extract of gelsemium, a little water is added and this constitutes the first dose. I then order him to bed, with strict injunction not to leave under any circumstances.

I am at his bedside again at the end of four hours; find the pulse a little softer, not quite so frequent; the skin a little cooler and thirst not quite so great. I now give a smaller dose two drops of the fluid extract of aconite, and ten drops of the fluid extract of gelsemium, and I say to my patient: "I will see you again at the end of four hours, when in all probability you will be bathed in a profuse perspiration, your headache and backache greatly relieved, and in every way feeling better, but under no circumstances remove any of your covering, lie still and sweat until I see you again, drink no lemonade, but a swallow of cold water (not iced water) may be taken occasionally.

When I see my patient again at the end of another four hours I generally find him in a profuse perspiration, headache all gone, or greatly relieved, all pains and aches much better, pulse normal in size and frequency; temperature 98.5°. This is the end of his grip, as a rule, but in case I find on my third visit that the pulse is still a little full, and the perspiration slight (perhaps none, but this is very rarely so), I repeat the dose, two drops of the aconite and eight drops of the gelsemium, and on my next (third) visit, after another interval of four hours, I find the treatment has accomplished the great essential, complete relaxation of the system and "restoration of equilibrium" in the circulatory and nervous systems, and there follows as a

necessity normal pulse, normal skin, normal temperature, normal respiration, and normal everything. A fourth dose is scarcely ever required, and I believe I have not found it necessary but in four or five cases out of more than two hundred.

It is the combination and careful administration of these powerful remedies that I have found such perfect success following their administration in *every case.* A little backache may linger in a few cases for twenty-four hours thereafter, and a sense of soreness all over the body is, of course, to be expected for a while after convalescence, but a small dose of the gelsemium (three or four drops) removes the backache, whilst a rubbing of the body all over with the hand, and olive oil, is exceedingly grateful to the patient. This must be done by the nurse passing his or her hand under the bedding, in order to avoid any possibility of taking cold. The hand of the nurse must be warm and the oil as hot as the hand will bear. I used this remedy on "general principles" in the first case I treated in the epidemic of 1889, and have used it in our present epidemic, and have nothing more to desire in the way of a *specific treatment.* I know of no serious disease which yields so promptly and permanently, and which has engendered so many feelings of gratitude from my patients as in the treatment of this disease by old-fashioned, common-sense method. I have not had a case of pneumonia nor anything else following this disease. My patients get sound and well and remain so.

A few precautions are necessary. The perspiration will generally last twenty-four hours or longer after the disease is broken up, and I forbid the patient getting out of bed for three days, and not to leave the house for a week. I give no purgatives prior to the third day of convalescence, and usually by that time they are not required, the bowels moving naturally. I seldom give tonics, as the appetite becomes ravenous, and digestion and assimilation perfect, which is the best of all tonics. I *never prescribe* this medicine for the patient to take himself, *and never leave a second dose with the patient to be taken at his own discretion.* I give *every dose myself, and never give a second until I am satisfied the former dose has done all it can,* for I have frequently found *a single dose* accomplish all that is required. A possible idiosyncrasy on the part of the patient must not be forgotten. No toxic symptoms have manifested themselves in any of my cases, but the intelligent physician will readily understand that he cannot be too cautious when handling such potent remedies in heroic doses. Professional brethren, please try this treatment (following the directions to the letter) in genuine la grippe, the worse the case the better, and report results to THE MEDICAL AND SURGICAL REPORTER.

ADDENDUM.

I have found that gelsemium alone is an abortive for la grippe in its *milder form, when there is little or no fever.* A general feeling of malaise, with wandering pains in the head, eyes, and body. What might with propriety be called grippy sensations. Two or three five (5) drop doses of fluid extract gelsemium, repeated at intervals of two hours, will seldom fail to afford complete relief.

The distressing bronchial cough, with a sense of pain and oppression in the lungs and throat, which accompanies so many cases of influenza is soon relieved by mustard plaster on the chest and the following expectorant mixture:

℞

Muriate of Ammonia c.p	ʒ iii
Morphia Sulphate	gr. iii
Spirit of Chloroform	ʒ i
Tr. Scillae	ʒ ii
Syr Senega	ʒ i
Sp. Rock Candy	q. s. add ʒ iv

Mix. A teaspoonful in water every two or three hours.

PERITONITIS.*

BY X. O. WERDER, M. D.,
PITTSBURGH, PA.

While peritonitis, as a disease, was well known to physicians of all ages, a full knowledge of its pathology and an intelligent method of treatment is clearly the work of modern investigators. Its etiology particularly was very little understood until the phenomenal advances in abdominal surgery cleared the darkness and threw light into the mysteries hidden in the abdominal cavity. Hand in hand with the surgeon worked the pathologist, and their combined efforts brought about a revolution of our views of the disease and its treatment. In no branch of medicine has such wonderful progress been made as in that pertaining to the peritoneum and the organs it invests. It is true this progress has benefited surgery much more than medicine; so it appears that peritonitis, at least many of its forms, is rapidly becoming a surgical disease. The diagnosis of peritonitis does not satisfy the progressive mind of the modern physician; he has

* Read before the Allegheny Medical Society, Nov. 17, 1891.

learned the importance of striving to arrive at its cause and seat which, though *contained* in that large cavity invested by peritoneal membrane, may *belong to* any of the many organs located there. Peritonitis is, therefore, a general name for many diseases, differing not only in their symptoms, pathology and etiology, but frequently also in their treatment. They are only alike in as much as they are all accompanied by inflammation of the *lining* membrane of the diseased organs, the investing peritoneum.

To enter into a detailed description of all these forms of peritonitis would be a task impossible to me without transgressing the limits of my time. I, therefore, decided to confine my remarks to two large groups of this disease which are by far the most frequent and important, the one affecting with particular predilection the male sex, especially the younger portion of it; the other is, exclusively, a female disease. I refer to peri-typhlitis or, more correctly, appendicitis and pelvic peritonitis.

Formerly most inflammatory conditions in the right illiac fossa were regarded as a typhlitis or peri-typhlitis, the former being a catarrhal inflammation of the mucous membrane of the cæcum, the latter an extension of this inflammation to its surrounding peritoneal covering and especially of the retro-peritoneal connective tissue of the cæcum, which was frequently accompanied by abscess formation in this retro-peritoneal tissue, caused generally by perforation of the cæcum through its posterior wall. These collections of pus were, therefore, thought to be outside of the peritoneal cavity. Disease of the appendix was much less connected with inflammation in the right iliac fossa. Within the last few years our views have experienced a decided change, principally influenced through the experience gained by the numerous abdominal sections made for this disease. Inflammation of the cæcum or peri-typhlitis is now regarded as very rare, at least on the primary lesion, while appendicitis is extremely common. McBurney says that in a hundred cases of inflammation in the ilio-cæcal region, ninety-nine are cases of appendicitis.

An appendicitis may be a simple catarrhal inflammation of the mucous membrane of the appendix vermiformis, causing few or no symptoms, excepting, perhaps, some slight tenderness over the region, which may be easily overlooked, accompanied by more or less disturbance of the digestive organs and often some febrile symptoms. The appendix in such cases generally contain small fecal concretions which act as irritants to the mucous surface and are accused of bringing on the inflammatory trouble, though in eight cases operated on by Lewis A. Stimson in only one were there concretions of sufficient size to be justly blamed for the existing condition. Foreign bodies, such as cherry pits, grape seeds, etc., are much rarer the cause than was usually supposed, and according to Jacobi, it is probable that "few, if any, foreign bodies enter the process unless the latter has previously lost its elasticity and contractility by an inflammatory change." This catarrhal inflammation may be followed by a complete resolution and permanent cure, but in many cases frequent relapses occur. The appendix may not be able to rid itself of these irritating fecal concretions, or the previous inflammation may have left a stricture at its cæcal orifice followed by retention of its own secretion, which may give rise to renewed attacks of inflammation, especially if excited by some traumatic influence. This may not confine itself to the mucous membrane, but extend to the submucous tissues and serous coat. Lymph is thrown out over its neighboring structure and adhesions are formed, encapsulating the original seat of disease, the appendix, and surrounding it by a barrier intended by nature to protect the general peritoneal cavity, should ulceration and perforation result in the appendix. An abscess now forming would, contrary to olden teachings, be intra-peritoneal, though not communicating with the general peritoneal cavity; loops of intestines glued together may form the abscess wall and prevent general septic peritonitis and death. The mass often felt in the right iliac fossa is nothing else than this exudation surrounding the diseased appendix which may have become organized into a distinct abscess wall. When inflammation and perforation come on suddenly and before nature has time to protect the general peritoneal cavity by such a provisional lymph-barrier, a violent septic peritonitis is the result, with death in two or three days. The autopsy of such a case I witnessed three or four months ago. The subject was a young, vigorous man who was taken severely sick with peritonitis and died at the end of the third day. The whole abdominal cavity was in the condition of septic inflammation; the appendix was perforated and sloughing, containing a cherry pit, and the cæcum almost gangrenous and also perforated. In such cases there generally have been previous attacks of appendicitis, though in this instance no history of such could be obtained.

If an abscess has formed the pus may find its way under the abdominal walls or into the retro-peritoneal tissues, or it may rupture into the general peritoneal cavity, or into an intestine. Within three months I have seen two cases with rupture into the bowel. In one, a boy of 16 years, the only thing he complained of when he consulted me was inability to walk on account of stiffness and contraction of the flexor muscles of the thigh. An examination revealed a deeply seated mass in the right iliac fossa, tender on pressure. As this mass, in spite of rest and appropriate treatment, increased in size, it was decided to operate. On the morning of the day set for operation he had a number of stools containing evidences of pus, and the mass had almost disappeared. The other case had two attacks of appendicitis within three months, during the second of which the abscess ruptured into the bowel. In both this accident was followed by rapid recovery.

The disease may produce no symptoms outside of those of an ordinary indigestion, so long as it is confined to the mucous surface of the appendix. Severe symptoms point to a more violent inflammation not confined to the appendix alone. Such cases may be ushered in by vomiting, and sometimes purging, accompanied with severe pains, particularly in the ilio-cæcal region; the pulse is accelerated, temperature often high, face anxious. On pressure we find tenderness over the seat of the disease, the abdominal muscles over the region are tense and rigid. Tympanites may supervene. These symptoms may continue three or four days and then gradually subside. In many cases a tumor can be felt in the region of the appendix. If these symptoms continue unabated beyond the third or fourth day, especially if tympanites increase, the pains remain severe, the pulse becomes accelerated, the temperature rises to 102° or 103°, perforation and formation of abscess may be looked for. Cases beginning with violent symptoms, intense pain, severe vomiting, marked tympanites, great tenderness in the ilio-cæcal region, which rapidly spreads over the whole abdomen, rapid pulse, are of the gravest nature and denote perforation into the general peritoneal cavity. A pulse of over 120, with rapid breathing, slight cyanosis, are extremely bad prognostic symptoms, as they are the expression of toxic effect on the action of the heart.

Frequently appendicitis does not have a typical course, and its diagnosis may be very difficult. The pain may be referred to other parts of the abdomen, the cæcum being such a movable organ that displacement and change of position is not infrequent. Then again it may be disguised by other symptoms or complications, such as strangulation or obstruction of the bowels. Ransohoff reports twelve cases in which appendicitis ran its course without any other symptoms than those of internal strangulation of the bowels. Hartly also reports two cases in which an operation was performed for internal strangulation, which proved to be intestinal obstruction from adhesions to the wall of an abscess formed by a gangrenous appendix. It would, therefore, be well in all obscure acute cases of abdominal troubles to keep in mind how frequently appendicitis bears a causative relation to many of these acute affections of the peritoneum. In obscure cases "McBurney's point" may be of some diagnostic value. In McBurney's experience in every case "the seat of greatest pain, determined by the *pressure of one finger*, has been exactly between an inch and a half and two inches from the anterior superior spinous process of the ilium on a straight line drawn from the process to the umbilicus. This point indicates the base of the appendix where it arises from the cæcum, but does not demonstrate that its chief point of disease is there."

The large majority of cases of appendicitis recover. Statistics in regard to the mortality of the disease differ greatly, however. It is a remarkable fact that German statistics show a much more favorable prognosis than those of America. Dr. Fred Lange, of New York, thinks that either appendicitis in America is more fatal than in Germany, or else the very severe cases in that country do not go to the hospitals, from which such statistics are derived. He says "Americans eat much, particularly concentrated food, masticate very little, and suffer from constipation," and are, therefore, particularly liable to this disease. Renvers treated at the University Clinic in Berlin, within four years, fifty-four cases, of which three died. It is also stated that out of 2,000 cases of inflammatory conditions in the right iliac fossa in the German army, 96 per cent. recovered without operation. Nothnagel treated at his clinic in Vienna from 1882 to 1890, 65 cases—55 men and 10 women, two-thirds of them between the ages of 11 and 30 years, with a mortality of three. Matterstock, however, gives, out of 177 cases, 30 per cent. mortality, of 70 children under 15 years, 70 per cent. Fitz, in the "Transactions of the Association of American

Physicians," states that he observed 72 cases, of which 74 per cent. recovered and 26 per cent. died.

Simple cases of catarrhal appendicitis usually make a speedy recovery under treatment by absolute rest in bed, restricted diet, laxatives, particularly calomel or the salines, morphine, hypodermatically if absolutely required for pain, hot fomentations and possibly leeches. It is the severe forms that give the physician greatest anxiety and tax his skill to the utmost. The greatest difficulty is to decide when to interfere surgically. Unfortunately, the symptoms are only too often unreliable guides; often when the symptoms indicate the necessity for operation the patient has already passed beyond the hope of relief.

Lewis A. Stimson says: "We have no means of distinguishing those cases which will go on to the formation of an abscess without accident from those in which evolution will be gravely interrupted." He, therefore, recommends early laparotomy (within the first three days), as it enables us to avert the process by the removal of the cause, and regards it as less dangerous than the expectant treatment. McBurney states: "The pathological condition of the appendix as compared with the symptoms in my own cases most positively show that one cannot with accuracy determine from the symptoms the extent and severity of the disease." Mynter says: "That we are utterly unable to judge correctly from the symptoms alone of the extent and severity of the appendix lesions and for this reason alone abdominal section must be the safest method of treatment." I believe that the advice of Thos. S. R. Morton, who, in connection with his father, Thos. G. Morton, has devoted considerable attention to this disease, and whose experience in the surgical treatment of this disease has been quite extensive, is not only good, but sufficiently conservative to meet the approval of the non-operative physician. It is, "to operate not later than the third day of the disease, if the patient up to that time has failed to markedly improve, under rest, restricted diet, purgation and topical applications. Especially should this rule be adhered to in cases where we have failed to move the bowels—they are apt to be of the fatal cases. Further than this we should invariably operate as soon as the presence of pus is assured; when peritonitis is developing and spreading; when signs of sudden rupture of an abscess into the peritoneal cavity appear, and when septicæmia from septic absorption is taking place. In children operation must often be done earlier than in adults, as in them the malady is more speedy in development, more fatal in tendency and shows greater proclivity to involve the general peritoneal cavity." (Thos. S. R. Morton, Philadelphia County Society, Sept. 28, 1891.)

Pelvic peritonitis is the most common form of peritoneal inflammation in the female. It is most frequently localized with a tendency to remain so, and follows an essentially chronic course, with occasional acute exacerbations. More so even than appendicitis is it characterized by frequent relapses. One-third of all gynæcological cases are victims of this disease. Bande found residue of circumscribed peritonitis in more than half of all female cadavers, Winkel in more than 33 per cent., A. Martin in 122 out of 287 cases of tubal disease.

The cause of pelvic peritonitis or perimetritis, as it is also called, in a large majority of cases, is diseased tubes. This is a fact which has only been learned quite recently. Most inflammatory conditions in the pelvis were thought to originate in the cellular tissue, and from there sometimes to invade the peritoneum; cellulitis was, therefore, the primary and most important disease. Not later than six years ago, Emmet, in the last edition of his work on Diseases of Women, says: "I shall employ the term 'cellulitis' in expressing the most common condition of pelvic inflammation in connection with non-puerperal diseases of women. Pelvic peritonitis will not be treated of as a distinct lesion, but as an accident, rendering the case of cellulitis more grave in character from this complication." The first description of the true pathology of pelvic inflammation was given us by Bernutz and Goupil, over thirty years ago, who, by a careful examination of ninety-nine cases, both during life and in the post-mortem room, pointed out very clearly that it was not the cellular tissue which was involved in this inflammation, but the peritoneum and that the cause of it originated in the fallopian tubes. Their teaching, however, was entirely ignored until operative surgery has opened up the peritoneal cavity to daily explorations and found the conditions exactly as described by these investigators. The masses and indurations generally found in the pelvis by bi-manual examinations and spoken of as exudations in the pelvic cellular tissue can be removed by the surgeon from the peritoneal cavity; they do not involve the cellular tissue to any extent,

but consist of ovaries and tubes folded upon themselves, matted together by exudation and adherent to the posterior surface of the broad ligament of the uterus. Frequently we find also intestines and omentum or an appendix as a part of the tumor. Polk, in 1886, in a paper on the "study of sixteen cases of so-called pelvic inflammation, known as 'pelvic cellulitis,'" states that abdominal section was made in all these cases and the lesions found were salpingitis, peri-ovaritis and pelvic peritonitis. In two of ten cases there was slight œdematous swelling of the cellular tissue in the broad ligaments, just beneath the spot at which an inflamed tube had rested; in the remainder the most careful examination failed to detect the slightest induration or swelling in any part of the cellular tissue that lay about the uterus or between the layers of the broad ligaments.

Dr. N. C. Coe (*Exaggerated Importance of Minor Pelvic Inflammations*) says: "Of half a dozen fatal cases of hysterotrachelorrhaphy and incision of the cervix in which I enjoyed the rare opportunity of studying carefully the sequence, in every instance the cause of death was acute diffuse peritonitis." In regard to the more chronic cases to which circumscribed areas of inflammatory exudations were found, he states that "peritonitis is certainly the most prominent element in most of these cases, so far as the post-mortem appearances afford any light;" and again, "By far the greatest number of these indurations are situated high up in the broad ligaments and consist of cicatricial masses, mostly confined to the peritoneum of tubes and ovaries surrounded by old adhesions, or occasionally an imprisoned knuckle of intestine. I confess that I have rarely (perhaps half a dozen times) found such thickening in the cadaver which could be inferred to a pure and straightforward cellulitis, and this, too, when I have recognized by the vaginal touch (before and after death) what seemed to be an induration, a distinct band extending outward from a deep laceration of the cervix, or a condition of tension in or above one lateral cul-de-sac, which did not exist on the opposite side."

Joseph Price, who has been in the abdominal cavity oftener than any other American surgeon, says: "The operative gynæcologist does not find any pelvic cellulitis." Lawson Tait is equally emphatic on this subject.

Having established that cellulitis is a rare disease, at least outside of the puerperium, and that what we used to regard as such is in reality, in the large majority of cases, a pelvic peritonitis from the outset, we will now briefly inquire into the etiology of the latter. A diseased tube is usually the focus from which the peritoneal infection starts. Disease of the appendages may have preceded the attack of peritonitis for weeks or months when a leaky tube may precipitate a peritonitis, that is, the secretion pent up in the tube may discharge through the abdominal orifice of the tube into the peritoneal cavity, as the result of hyperdistension, trauma, violent exertion, etc. Or the tubal disease may arise acutely, and extend at once to the peritoneum, the most common causes in producing inflammation of the uterine adnexa puerpual infection, gonorrhœa, extension of an endomitritis to the tubal mucous membrane, a catching cold, especially during menstruation, etc. Unskillful intra-uterine treatment, minor operations about the cervix, such as Emmet's operation, dilatation, etc, especially if done without the strictest antiseptic precautions, are frequently followed by salpingitis and subsequently peritonitis; the introduction of an unclean sound, especially if it produce a lesion to the mucous or muscular surface of the uterus frequently results in pelvic inflammation. The symptoms of pelvic peritonitis vary considerably in intensity. While often so mild as to escape our attention, its onset may, especially if due to a leaky pus-tube, be so sudden, severe, and violent as to resemble a peritonitis following perforation. The disease is usually ushered in by a chill, fever, more or less severe pains in the lower part of the abdomen, back, and thighs; irritability of the bladder, sometimes rectal tenesmus. The hypogastric region is tender on pressure and vaginal examination very painful. Within forty-eight hours a swelling may be noticed on bi-manual examination, which, in a few days, may reach to the umbilicus. It is, at first, soft, baggy, almost fluctuating, but gradually becomes firmer until it often appears as hard as a board.

Under rest, opiates to relieve suffering, hot fomentations, and, after the febrile symptoms have subsided, the iodides, internally, and tonics, and the local application of iodine over the abdomen and to the vaginal vault, hot douches, glycerine tampons, iodoform, ichthyol, etc., the exudation gradually decreases, until after a few weeks or months it has become imperceptible. The patient's appetite has improved, her pains have lessened or disappeared entirely, she is gaining flesh, and regards herself as cured. The inflammation, however, does not always run such a smooth course. Instead of ending in resolution it may go on to suppuration. Abscesses

form and may discharge through vagina, rectum, bladder, abdominal walls, or intestines. They may then heal spontaneously, very rapidly, or they may continue to discharge indefinitely, until the patient dies from exhaustion or sepsis, unless surgical measures are adopted. Even if the disease ends in resolution, this does not always mean cure. On the contrary, it is often followed by a life of misery and suffering. When the patient returns to her ordinary duties she finds she is unable to fulfill them. She has aching in her back, abdominal pains, increased on slight exertion, disturbance of her gastric functions, and other reflex symptoms. Her menses are more profuse than formerly and more painful, marital relations are accompanied with suffering or may have become utterly unbearable; in that she presents the picture only too familiar to every physician practicing in gynæcology. Examination reveals extreme tenderness over one or both uterine adnexa; perhaps some thickening in the region of tube and ovary, or you may find large masses in the region of tube and ovary and filling up Douglas' pouch. In other words, while all active peritoneal inflammation may have subsided, the focus of the disease, the diseased appendages have remained and wait only a favorable opportunity to light up another acute pelvic peritonitis. I have seen three and four such attacks within one year. Such cases will probably go on from bad to worse until these diseased appendages are removed.

For the sake of convenience the results of pelvic inflammation may be tabulated in five groups.

1. Complete resolution and recovery. Such cases are restored to perfect health and are able to bear children.

2. Adhesions about ovaries and tubes which, however, do not affect the general health of the patient, but are frequently associated with sterility.

3. Recovery with a catarrhal salpingitis and possibly oöphoritis, which, under proper but often prolonged treatment, improve and often get perfectly well.

4. Includes cases of old and obstinate forms of salpingitis, hydrosalpinx and oöphoritis, who pass from one physician to another, or from one quack to another, and are doomed to permanent invalidism, unless relieved by the removal of the diseased organs.

5. And last are principally the victims of grave puerperal affection or gonorrhœa, suffering from pyosalpinx and ovarian abscess, which are certainly threatening their lives and are only curable by laparotomy.

In concluding this rather lengthy paper I make no claims to originality or thoroughness in treating this important subject. I am well aware that it is merely a fragmentary exposition of the subject presented. Many points that seemed of particular importance to me have been dealt upon rather in detail, while others, undoubtedly appearing equally or more important to some of you, I have only touched upon. Any omissions in this paper will, without doubt, be supplied in the discussion, which, I hope, will be full and exhaustive. (*For discussion, see Society Reports.*)

GUMMA OF THE IRIS.

BY FLORENCE MAYS, M. D.,
PHILADELPHIA.

Through the courtesy of Dr. Edward Jackson, Surgeon to Will's Eye Hospital, I report the following case, which is of interest, combining as it does so many ocular conditions, the results of syphilis, viz., iritis gumma of iris, hypopyon, keratitis punctata and papillitis:

F. C——, aged 19 years, came to Dr. Jackson's Clinic, Will's Eye Hospital, June 27, 1891, saying that his left eye had been inflamed and painful for three weeks. His right eye had been sore one month before. The following specific history was elicited: He had had an initial lesion six months before, one month after exposure. The secondary symptoms, such as glandular enlargements and mucous patches of mouth and fauces followed. At this time the patient was suffering from acute coryza. Said that he caught cold one week before. As he had been taking no medicine the coryza could not be attributed to the effect of potassium iodide.

O. D. Sub-acute hyperæmia of reflected and tarcal conjunctiva. Pupil, 4 mm. in diameter and normal. Globe, normal. V = $\frac{5}{viii}$.

O. S. Intense inflammation of tarsal and reflected conjunctiva, extending up to cornea with marked pericorneal zone. Moderate-sized ulcer on conjunctiva between inner canthus and cornea. Cornea hazy. Anterior chamber deepened with hypopyon below. A yellowish gumma 6 x 4 mm. in diameter, with vessels upon it, upon the upper nasal quadrant of iris. Gumma somewhat wider than iris and extending well forward. Pupil irregularly oval, long axis 30°. Iris yellowish-green. Iris of O. D., gray hazle. V= perception of moving fingers four inches from the eye.

Ophthalmoscopic examination: O. D. Low H. Disc reddened and swollen. Disc

margins almost entirely obscured. Arterial sheaths marked beyond disc.

O. S. Very indistinct fundus reflex. Punctate opacities marked in lower part of cornea.

The patient was ordered calomel gr. ¼ t.d. by the mouth, and one drop of four grain solution of sulphate of atropine in O. S. t.d. He was also directed to use hot compresses.

Five days later, July 2, the patient returned improved and was given protiodide of mercury, gr. ⅓ t. d., in place of the calomel, and told to gradually increase the dose.

July 7, he was much improved, and was given a solution of sulphate of hyoscyamine for the purpose of determining the refraction of O. D.

July 9. C. Hyos. O. D. V = $\frac{5}{vii}$ + 0.50 D. Sph ⌒ + 0.25 cy. ax. 90° = $\frac{5}{v}$.

July 16. Patient was taking five grains of protiodide of mercury daily. Gumma entirely absorbed. Coloboma of iris at former seat of gumma. Pupil key-hole and semi-dilated. Pericorneal zone still present.

The patient ceased to visit the clinic at this time, so no further opportunity for the study of the case was afforded.

414 W. Huntingdon St.

THE ACTION OF OREXIN ON THE STOMACH.

Dr. W. Brunner, in *Gazette Lekarska*, March 14, 1891, gives his experience with the use of orexin and its action upon the stomach.

His experiments were made upon thirty persons (180 separate observations). The doses employed were 0.25 to 0.30 gramme, in pills or capsules, two or three times daily.

In four healthy persons pain in the epigastrimes and vomiting appeared after the second dose was taken.

In twelve neurasthenic and hysterical patients, with impaired mechanical action of the stomach, the appetite was increased in six; this did not last long, for upon stopping the use of the drug, the appetite became poorer than before, with pain in the stomach and severe ringing in the ears. In another group of ten cases (patients with consumption, rheumatism, and cardiac disease) the effect was also doubtful. In four cases of gastric diseases (one catarrh, two cancer, and one dilatation) the pain and vomiting were aggravated.

In view of these experiments, the author recommends that orexin be dropped entirely from the list of reliable medicinal remedies.

SOCIETY REPORTS.

ALLEGHENY COUNTY MEDICAL SOCIETY.

J. J. Green, M. D., President pro tem., in the Chair.

Scientific Meeting, November 17, 1891.

Dr. X. O. Werder read a paper on Peritonitis. (See page 173).

Dr. Baten: I do not think I can say anything new on the subject. The disease, however, is not so old as the reader would lead us to believe. The Italian physicians in the latter part of the seventeenth and the beginning of the eighteenth century were the first who gave some of the symptoms of the disease. They studied the disease and made the diagnosis of peritonitis. Cullen, in 1775, mentions the disease, but does not describe it. Gast said in 1809 that the symptoms of the disease had been truly known for only twenty years, so that we did not have a true history of peritonitis until 1789.

I have had two cases of the disease which he describes, that is, I suppose it would be classed under that disease, pelvic peritonitis. It requires a good deal of time to make out the disease. I remember in these two cases I attended—and I had a good diagnostician to see the cases with me—we were unable to make out the disease until nearly the end of the second or third week. One case, however, went on, and an abscess was formed and opened, and the pus let out and the patient recovered. In regard to the existence of these diseases, I have no doubt they exist a great deal more frequently than we have any idea of or even suspect, and a great many patients likely go on without any treatment whatever, or any successful treatment, and remain as invalids the remainder of their lives, if they do not come in contact with some one who can make out a proper diagnosis.

Dr. Macfarlane: I listened with a great deal of pleasure to the doctor's paper. Whilst septic peritonitis is more common than the majority of the profession appreciate, possibly owing to inability to diagnose it, I think very many medical men recognize trouble about the appendix, even though no tumor can be found in the region. I think sometimes the trouble is referred to the appendix, mistakenly. Still the matter is, of course

more or less common. About the location of the appendix, by the aid of McBurney's point, it was my pleasure to read quite a lengthy discussion upon the matter. It was pointed out by an anatmoist that the base of the appendix rotates upon two or three planes and never upon one point. Although I believe it does nothing more, McBurney's point will serve a purpose in attracting attention to the region more than has been done heretofore. I think the teaching of older medical men had a good deal to do with the mortality in these cases, for the very reason that they were thoroughly imbued with the idea that when you have disease of the intestine you are to place the intestine in a splint with opium, and while the patient is relieved from pain the mischief is going on there in spite of the opium. While laxatives may be abused, I think that very frequently, especially by the use of calomel, good could be done with them at the outset, and very many cases are cured with the use of purgatives and hot applications and rest in bed, whilst if the opium treatment is continued to any excess, just what you want to avoid, that is, the accumulation of fecal matter in and around the parts, will result disastrously.

Dr. Buchanan: One or two points I think might be dwelt on a little more at length than has been done this evening. I suppose it would be right to confine the discussion to the matter which has been presented by the gentleman who opened the discussion—the subject of appendicitis and pelvic peritonitis. These two subjects illustrate the advance which the gynæcologist has made in medicine. On the subject of appendicitis all medical men are pretty well versed; they do not require the services of a specialist to give them any information; whereas, when they come to examine the ovaries and tubes, many otherwise well-informed practitioners are all at sea. It is because they are not accustomed to the bi-manual method of examination; they are not in the habit of taking these parts between their fingers and finding out what they hold. In most cases of pericecal abscess operation is readily acceded to, while in many ovarian and tubal abscesses they frequently object to the opening of the abdomen for the removal of these abscesses, because they have no familiarity with the examinations necessary to demonstrate the condition.

In inflammation of the appendix, I believe that wherever there is a tumor to be demonstrated, there is always localized peritonitis and the cases can be grouped into three classes:

First, those in which the inflammatory collection is such as to give rise to a tumor which can be felt, and which goes on to resolution. These are the great majority of cases, and for that reason alone I think it would be unwise to treat all cases by abdominal section. Statistics given are to the effect that a very large percentage of cases get well with merely palliative treatment.

The second class of cases includes those in which the peritonitis goes on to the formation of a localized abscess. This abscess sometimes opens spontaneously, occasionally through the bowels; when an incision is required, it is often merely the opening of an abscess, the peritoneal cavity not being invaded.

The third class of cases comprises those where no local abscess is formed, but where the first peritonitis is a general peritonitis, and these are the unfortunate or fatal cases that Dr. Werder has spoken of, and he gives a reason for the difference; for one being localized and the other generalized peritonitis. The peritonitis has not had time to shut off the disturbing element and encapsulate it in an abscess. I will make a suggestion in these cases. It is not the element of time that makes the difference, but the nature of the material that excites the peritonitis. A perforation may be made and no streptococci or other virulent germs may have entered. In this case it is a non-septic peritonitis, therefore a local peritonitis; for the same reason that, in cases of gonorrhœal salpingitis, attacks of local peritonitis are common. The gonococcus may enter the peritoneal cavity, and it has been pretty well established that when it does enter that cavity it is not an extremely dangerous visitor. It sets up a localized peritonitis, and these are the attacks of localized peritonitis that prostitutes have. Entirely different is the course of the peritonitis which arises from the bursting of an abscess, the result of infection at the time of confinement. Here the most virulent germs enter the cavity and give rise to a general peritonitis which may result fatally in a few days, possibly in a few hours. As I said before, the different course of the peritonitis in second and third stages of appendicitis, may not be due to the element of time, but it may be in the nature of the exciting cause of the peritonitis.

Now the subject of inflammation of the fallopian tubes which frequently gives rise to what is commonly recognized as pelvic peritonitis, is a subject which, I believe, in this part of the country has not received sufficient attention. I have seen within the last couple of years a good many cases where abscesses of the ovaries and tubes

could be demonstrated easily, and where the operation has not been recommended to the patient by the attending physician, even though attention was strongly called to it. I recall one case where a patient with an ovarian abscess was treated for malaria by a gentleman who is considered in the front rank of the profession in this city, until the abscess broke through the vagina. Now, that could only have come through lack of examination. Another case was one of gonorrhœal salpingitis, followed by very severe local peritonitis, in which a mass could be distinguished very easily after the peritonitis had subsided. This patient is now under electric treatment. Her doctor comes every day, or second day, and applies the battery. This woman has been about one and one-half years undergoing this and similar treatment and has not had a well day. Another case was treated by a most excellent physician in this city, one who stands very high, which I never saw but once and then at his request. This patient had probably an abscess, certainly as large as my fist. This woman had been carrying this abscess, according to accounts, for about three years. She was an invalid as most of these cases are. It was pitiable to see her turn in bed. This gentleman had not advised or apparently thought of an operation. He was much pleased at her being a little better than she was a month before. Another case I saw about a year ago in a neighboring town. She had an abscess that could be distinctly felt by any person who put his hand on the abdomen. This patient had been constantly in bed for two years, and in that time had not touched her feet on the floor. She has since died. I mention these cases because I believe that many others of similar character now exist in this and neighboring communities, and that this matter is not sufficiently talked of by the profession here.

Dr. Lange: The subject of peritonitis has been limited to pelvic peritonitis and appendicitis. I am at work at the present time upon a paper reporting a series of twelve cases of typhlitis, part of the number that I have treated during my professional life, and of which I have accurate and full notes. I will publish these cases as I complete them. I must state I have never lost a case of typhlitis. I stand with the Germans in this respect, if, as the reader of this paper stated, the mortality in Germany is very much lighter than in America. Of these twelve cases of which I have notes, one only received surgical treatment, and that was a simple incision through the bell-wall for the evacuation of pus. Dr. Werder seems to support the statement that after a duration of three days, the inflammation—typhlitis—not showing any apparent improvement, a section would be indicated. It strikes me that this is entirely too energetic, that it is, to say the least, unwarranted. This is all right when pus has been demonstrated. Otherwise it is not warranted, because we still sometimes have septic peritonitis after abdominal section with the most careful precaution by the most careful operator. In other words, antisepsis is not yet thoroughly understood nor mastered. As long as this is true, it is unwarranted to advocate incision in typhlitis because it does not improve after an existence of three days. The reason is not sufficient. It must still be the demonstration of pus. It is justifiable, however, to dilate the sphincters, enter the hand into the rectum and search for pus, because it forms frequently *behind* the cæcum, and when so, cannot be found by examination through the belly-wall.

Among the twelve cases I shall report is one in which the tumor was as large as a melon, where, upon careful and repeated examinations, no pus could ever be found. A deformity lasting almost two months after recovery existed by reason of extreme flexion of the thigh upon the abdomen during the inflammation, and the whole limb was infiltrated and œdematous from vein-pressure, and before the leg could be brought down and the tumor disappeared, had a duration of between three and four months. The recovery is perfect. I think I have a right to assume that no pus existed in that case, and I would, with all due regard for the opinion of the authority quoted by Dr. Werder and of Dr. Werder himself, insist that this rule is unjustifiable. The criterion, I think, must be the demonstration of the existence of pus. The treatment of general peritonitis has undergone some change. The change advocated in the last few years is the administration of purgatives, particularly the sulphate of magnesium instead of opium. I believe that general septic peritonitis is always fatal, and I believe we often speak of general septic peritonitis where it does not exist, as for instance: I was recently concerned in a case where an abdominal section was done, and on the third day it was concluded that the patient had general septic peritonitis. She was given, at my earnest solicitation, morphine. The sulphate of magnesium treatment was ruled out by my insistance, and she recovered. I was doubtful of it at the time, and now I do not believe she had septic peritonitis. One case of septic

peritonitis I remember very distinctly, occurred five or six years ago. A patient came to my office in the middle of the night out of breath, said his neighbor was very sick, and took me to his bedside. I went with this man for a distance of three blocks, and found the patient with an extremely bad case of cholera morbus. I gave him morphine, remained with him about half an hour, and when he was better, the wife of the messenger came to me, and said: "Doctor, my husband has the same thing." I went into the adjoining house, and found this patient with apparently a very severe attack of cholera morbus; but it was septic general peritonitis, and killed him in forty-eight hours. Here were two cases occurring at the same time and side by side, and, though I may lack special acuteness, I could see no difference between them. It was impossible for me to say that one had a certainly fatal affection and the other a temporary slight illness without any mortality. This was true until the effects of morphine decided one to be cholera morbus. Both were chilled, both were shocked, both were very tender and tympanitic, both drew up their legs, both were cold and blue and almost pulseless, and both had death in their faces. Both also vomited and purged, and both were evidently in unutterable anguish. I could appreciate no difference between them. From this and like evidence, I believe a diagnosis of general septic peritonitis is not always correct; and further, that when such a patient has recovered under the magnesium treatment, no general peritonitis existed. I am told by a laparotomist of large experience that most of his women on the third or fourth day have such an attack; that he gives them magnesium and they get well. But this is certainly not general septic peritonitis. I believe it is a colic with meteorism from handling or exposing the bowels; a condition analogous to that frequently seen after hard protracted labor, and in such cases the magnesium treatment is excellent. But in my opinion, a patient with septic peritonitis dies. There are two ways, generally, by which septic inflammatory agents reach the peritoneum: by ulceration through the stomach or intestinal tract, and in women from the genitalia. The messenger for the cholera morbus man probably had some ulcer of the bowels, perhaps painless, with a perforation which happened through his violent run to my office that night. No *post mortem* was had. One thing that appears from Dr. Werder's paper and the discussion is that no one mentioned idiopathic peritonitis. I believe there is no such peritonitis. The messenger of whom I spoke was seen by other physicians, and the conclusion was that he died of idiopathic peritonitis. But this was many years ago, and, barring puerperal and traumatic inflammations of the peritoneum, all others were idiopathic. We know better now. As to the treatment of this septic inflammation of the peritoneum, if there be a chance to benefit patients, I believe it to be by opium, and very slight. Dr. Andrew Clark, as all the world knows, was a very eminent physician, and he reported a number of cases of acute general peritonitis cured by the opium treatment. I do not know whether that is correct. It possibly is, but from what I have seen, I must doubt it. As to what I have seen of magnesium treatment in cases where the diagnosis was certain, I must condemn it. Can you do anything else when you think of typhoid or duodenal or gastric ulcer perforation? I believe the prognosis to be always extremely bad, and the only forlorn hope to be opening the belly and washing it out.

Dr. Macfarlane also objects to the opium treatment, to "putting the bowels in splints" in perityphlitis. I have here twelve cases of such peritoneal inflammation, all of which recovered and all of which were so treated. I have had additional cases of which I have no record, which were treated and which ended in the same manner. Therefore I shall continue so to treat them. But I do not use morphine alone; I do not trust to morphine alone. I use also calomel. We were wont to say for its alterative effects, now we give it for its antiseptic and antiplastic effects.

Dr. Kœnig: It seems to me Dr. Lange must have misunderstood Dr. Werder in regard to at least one assertion. He said Dr. Werder had not mentioned idiopathic peritonitis. If I am not mistaken, Dr. Werder declared that peritonitis might be produced as a result of "catching cold" at the time of the catamenial period. If that means anything else than idiopathic peritonitis, I fail to understand it. The term "catching cold," to my mind, is simply an admission of ignorance. I wish also to add the weight of my testimony in favor of the opium treatment. We want to relieve the nervous system of the irritation that the disease produces, and we can do it better by opium than by any other remedy. The late Professor Austin Flint was sometimes jestingly accused of having reduced his medication to the use of two drugs, whisky and opium, and I well remember his remarks regarding opium. In serious diseases, he admitted, it was not curative under the ordinary acceptation of that term, but he declared that

it was curative nevertheless, for the reason that it established a tolerance of the disease for the time being, allowing nature to repair the trouble under the reduced sensibility of the nervous system.

Dr. Grube: I can recall two cases which I think illustrate the fact that no one line of treatment can be laid down. Each case must be treated on its own merits. One case was of peritonitis which went along for some two weeks or more, until I was satisfied there was pus present. I demonstrated the presence of pus by the hypodermic needle, and then I operated. It was a very simple operation. I merely cut down through the muscles of the abdominal wall and met the abscess cavity, and, instead of cutting into it, I took the forceps and stretched it, and the pus came out, and that was the extent of the operation. Any physician can do that.

The next case was very much like it, and I thought I would have another opportunity for operation, for I had some of the surgical enthusiasm. I watched the case, and in about a week the whole thing disappeared without any pus at all. My idea of the treatment of all these cases is as Dr. Lange said. The time for operation is when you can demonstrate the presence of pus, and not until such time, with the exception of the cases where you have collapse, and if they are not operated on quickly, you have no chance of saving your patient. My own experience has been that each case has to be watched carefully. What is necessary in the case is simply opening the abscess, or else we will kill our patients very quickly.

Dr. McKibbon: The gentleman on my left has stated the history of two cases that he had. Dr. Senn, of Milwaukee, has given the history of the cases he treated. He claims the operation done in this condition is practically of very slight importance, and on the other hand, that by waiting for these cases to become bad is the worst treatment that can be pursued. He says the operation is not of sufficient magnitude to wait until there is something turning up.

Dr. Buchanan: I would like to express myself against making a fixed time for operation. I think, with Dr. Lange, that to fix absolutely on the third day as the time to operate if the patient is not improving, is rather arbitrary. I could submit a number of cases that got well without an operation. I have seen many cases that did badly for three days and eventually recovered without early interference. I think Dr. Lange has been wonderfully fortunate in the class of cases he has had, if he has had twelve consecutive recoveries. One of his cases would have been much better with an operation. I think very few of us would be willing to let such a mass go on, even to the size of a *small* melon, without opening it up and endeavoring to do away with the origin of this immense inflammatory exudate. I think there was pus in this case. According to the history given, this patient did not make a very pleasing recovery. I think Dr. Grube has very well stated the two classes of cases that should be submitted to operation, those in which pus can be demonstrated and those in which the perforation is through the appendix, and is setting up general peritonitis. If you can catch such cases in time, it is proper to remove the appendix and wash out the cavity. Usually they die.

Now, in repard to septic peritonitis. As I understand Dr. Lange, he makes the test of septic peritonitis the death of the patient. If he dies it was septic peritonitis, and if he recovers it was not septic peritonitis. I do not think this a fair way to test the method of treatment for that disease. If I had septic peritonitis, I would like to have some very vigorous treatment with epsom salts at first, and if that did not succeed very soon, I would be willing to take very large doses of opium.

The case which has been cited, in which marked improvement took place, which was supposed at first to be septic peritonitis and recovery occurred in three days, it seems to me, from the description of the symptoms, was one of beginning septic peritonitis. I think very likely if the operations of this gentlemen were all followed on the third or fourth day by the symptoms described by Dr. Lange, it was the result of septic conditions. It has been remarked that Dr. Sands always advocated the removal of the appendix. This is certainly proper in case you can find it, but you can not always get it. It is a nice thing to remove and a safe thing to remove; at the same time I do not think it is a very good thing to hunt for it. There is a great deal of change taking place in the surrounding parts which render it difficult to find. The rule that operations should be made parallel with and a short distance above Poupart's ligament is a very good rule, except in those cases where the abscess does not approach the ligament. There is a class of cases where the localized peritonitis occurs opposite the umbilicus or a little lower.

Dr. Lange: I do not set myself up as a judge concerning the case Dr. Buchanan has reference to, but merely submit my opinion.

I think the doctor will agree with me that if my associate in the case was correct when he said that nearly all his patients had such symptoms on the third or fourth day, that it was not septic peritonitis, because if all his patients had septic peritonitis and all got well, that gives a grand and new aspect to the whole matter. I did not believe at the time that it was septic peritonitis; recovery confirms that belief. I am entirely willing to put myself on record that when this inflammation does not kill, it is not septic and not general; in other words, that septic general peritonitis is fatal, despite opium, calomel, magnesium, or any drug that may be given; that when such a case ends in recovery it involves an error of diagnosis. Another point, the operation of opening an abscess, which I did in one of my twelve cases, is quite a different thing from opening the cavity on the third day of perityphlitis. There may be no pus-sac, no pus cavity; if not you will get into the general peritoneal cavity, easy enough in any event; if you do not, if you content yourself with cutting down to the tumor adherent all around, and do not free it, and palpate and examine it, you have accomplished nothing. Doing this thoroughly, all the chances are you will get in; and if you do not, and there is no pus, what have you accomplished? Nothing. The criterion still must be, pus or no pus.

Dr. Green: I want to say one word in regard to trying to make the distinction between septic and non-septic peritonitis. It seems to me in nearly all cases it can be detected by the general symptoms of the patient. I think the best guide is the condition of the patient. That is the general condition, and the general aspect of the patient. If the disease is of a bad nature, the patient will readily succumb. These are the symptoms I have allowed to guide me in all such cases, and I think no physician ought to find any trouble in distinguishing, after twenty-four hours, what kind of a case of peritonitis he is dealing with. I think twenty-four hours will determine the case, thirty-six hours at the utmost.

Dr. Werder: I am thankful for your kind consideration of my paper and also for the discussion of the subject. I have very few remarks to make, because the matter has been discussed so thoroughly that there is not much to be said. Only a few points I would mention. The first is in regard to McBurney's point. I have very little experience with it. Of course the appendix is a very movable organ, but Dr. Macfarlane claims that if you put the end of your finger at the point he claims as diagnostic, that that point touches the base of the vermiform appendix, and the base of it is always located in the same place unless the cæcum is displaced. It may be so, but if so, the displacement is very common. I know Dr. Clark claimed great results for the opium treatment. He gave opium simply according to effect only. If I am not mistaken he gave what are usually considered enormous doses, reducing the respirations in some cases to 10 or 12 per minute. Of course these are enormous doses. I think no one to-day gives those enormous doses, and I know our results are no worse than Dr. Clark's were. I prefer the calomel treatment. If I had peritonitis I would not want to suffer very much pain, I would want a dose of morphine, but as a routine treatment, I think I would prefer the purgative treatment. When opium is given the bowels confine the fecal matter, which contains septic germs, and some of these cannot help getting into the general abdominal cavity. Septic peritonitis has often been produced by an accumulation of fecal matter which could not be passed. Often cases of peritonitis are due to germs getting into the abdominal cavity through the bowels. Now purgation will carry that off.

Dr. Buchanan speaks of perforation of the vermiform appendix not always causing peritonitis, because it depended a good deal on the matter contained in the bowel, which then reaches the peritonal cavity. If it contained very malignant germs it would cause septic peritonitis. I believe that any perforation anywhere in the intestines or stomach, any perforation in the general peritoneal cavity, will produuce septic peritonitis very suddenly and rapidly. Dr. Lange spoke of twelve cases of peritonitis which he treated, all of which recovered. That is certainly very fortunate, and it is doubtful if his next twelve cases will be as fortunate. He may have a streak of bad luck in the treatment of these cases. I am certain a case of the kind of which I reported the post mortem will die, no matter under what treatmentt, and die very suddenly, unless something surgical is done at once. The difficulty is in deciding when to operate and whether to operate, and the difficulty is to ascertain the exact condition of the tumor. If there were any special indications to determine the conditions inside, then we would know exactly what to do. The case may look favorable, and at the same time a fatal accident is already present, and unless we operate early in such cases our results will be very bad.

If you wait three days, in some cases, the patient may be dead, but to say you must operate on the third day, is perhaps too arbitrary; on the other hand, the second day is very often too late. There are cases in which, if you want to give the patient any chance for life, you must operate the first day, as soon as you see the case, but the difficulty is, to tell that a case requires operation at once, and until we can make a more certain diagnosis, I think the surgeon is perfectly justified on the third or fourth day, if the patient is in a very dangerous condition, to remove the diseased appendix or abscess or pus. I think if he does that on the third or fourth day he will have a very small mortality. If he waits until the last day, then his mortality will probably be 100 per cent.; that is, if he waits, as one gentlemen here advised, until perforation or collapse sets in, there is no justification for operation and he need worry the family and patient no more. It is too late to operate. The gentleman also mentioned that pus should be demonstrated. If immediately under the abdominal wall, it is an easy thing to do, and in a case of that kind, puncture is hardly necessary. You can feel quite distinctly if pus is under the abdominal wall. If the pus is back of the cæcum and you run a needle into it and withdraw one, two or three drops of septic pus and smear it upon the the healthy peritoneum you can hardly help producing general septic peritonitis. I confess I lack courage to punch a needle back into the abdominal cavity, if I suspected pus. Dr. Lange also advises exploration through the rectum to find pus. That has been recommended by quite a number of persons, and it is practiced to a great extent, but we are to remember that these abscesses are frequently so very small that they may contain only a drachm or one or two ounces of pus, and even if you push your whole hand into the rectum, if the abscess contains only a drachm or two of pus, you would not be able to recognize it by palpation, and yet a drachm or two of pus, when it gets into the abdominal cavity, will be sufficient to cause death in twenty-four hours. Dr. Green speaks of the diagnosis of septic peritonitis by the general symptoms, pulse, expression, temperature, etc. He says septic peritonitis is not very difficult to diagnose and that every physician ought to have very little difficulty in making a diagnosis of simple from septic peritonitis. Probably in a majority of cases that is quite true, but many cases of septic peritonitis present very few symptoms and do not appear to be very sick patients at all. They may have no elevation of temperature; perhaps the only unfavorable sign you may notice in some of these cases is the very feeble pulse. I think this the most important diagnostic symptom in peritonitis, no matter whether the temperature is low or not. I do not think temperature has very much to do with the diagnosis, but a very rapid, feeble pulse and a lack of normal breathing, these are the most important symptoms and the most dangerous symptoms. Pains and temperature are not very important diagnostic points. Dr. Lange spoke of a case of cholera morbus and septic peritonitis, in which it was impossible to say, when he saw the cases, which of the two was the sicker man. The case in which I saw the post mortem examination began exactly like a case of cholera morbus. Violent vomiting, intense pains, and death in three days. He had a perforation of the appendix, perforation of the cæcum and pus all over the abdominal cavity. I suspect Dr. Lange's case to have been one of a similar kind.

Report of cases followed:—

Dr. Buchanan: Five years ago I saw a case of croup in which it was necessary to introduce a tube. I opened the child's windpipe and put in a black rubber tube. The child was two years old and in three or four days, if I recollect correctly, I removed the tube, but the child had so much difficulty in breathing that I replaced it and left it in until the expiration of a week. I again removed the tube, and again this hard breathing came on. Some time after that I removed the tube and succeeded in keeping it out for two or three hours. At the end of that time the hole had become so very small that it was with the greatest difficulty I succeeded in getting it back before the child strangled. At intervals afterwards I removed that tube, and I at one time started to shorten it, and I thought if I would replace it each time with a shorter one I would, at length, have no tube at all, but when I got down to a certain degree of shortness I found the child could not breathe. I sometimes did not see the child for six months or a year. I was called to see the child about a month ago, and found that he had spasmodic croup, and also, to all appearances, there was no air coming through the tube. I endeavored to extract the tube and found the granulations had grown down in the opening, and when I pulled it up these points of tissue acted as a hook to hold the tube in place. I allowed the tube to remain, feeling convinced the child would get over this attack of croup. I saw him incidentally last Sunday and then withdrew the tube as far as possible and clipped this point off and extracted the tube. This point was about

one-third or one-quarter of an inch long and as thick as a pen-holder. It was very tough tissue, covered with epithelium. The child since that time has been perfectly healthful. I mentioned this case about two or three years ago before this society, and I merely report the case now as closed. I would state that I saw this child this evening incidentally, and I believe the aperture is entirely closed, from the examination I made merely with my fingers, in endeavoring to open the parts up, and I believe the aperture has grown together. It now has been two and one-half days since the tube was taken out.

DR MACFARLANE: I saw Dr. McCann do this operation about fourteen years ago on a child named Murdock. He was two years of age, and had diphtheritic croup. The child got well, and when an attempt was made to take out the tube he was immediately seized with suffocation, and we were obliged to replace it as quickly as possible. That was a silver tube. One day when we had removed the tube, which had been in some time, the outer shell was corroded and all eaten away, and there was nothing left but a very small portion of the inner shell. It was replaced by a rubber instrument, and it remained in the parts for a number of years. The rubber tube remained in, to my knowledge, until a year ago. On one occasion the boy had gone into the water and had waded in till this aperture was under; he was then sixteen years of age. He immediately became suffocated, and had it not been for his brother, who came to his rescue, he would have succumbed.

COCAINE IN PERITONITIS.

Dr. Julius G. Kiefer states, in the *Kansas City Medical Index*, that the distressing pain and vomiting of peritonitis may be promptly checked by a suppository containing one grain each: extract of opium, cocaine hydrochlorate, and iodoform. It will be safe to use one suppository per rectum four hours apart, if the patient is closely watched for toxic effects, which may be noted by cold extremities and enfeebled heart action. I was led to the employment of the above on the theory of the malignancy of the affection and reversed peristaltic action of the bowel in peritonitis, and the well-known anæsthetic properties of cocaine on serous membranes. Alimentation should be temporarily suspended, and enema must be avoided until vomiting is checked.

Any discussion will be thankfully received.

SELECTED FORMULÆ.

OTALGIA.

The following is recommended (*Ugeskhift for Laeger*, Nos. 28 and 29, 1891) in otalgia:

℞ Chloral camphor.....grammes 5.
Glycerini..... " 30.
Ol. amygdalar. dulc..... " 10.

Dip a wad of cotton into the mixture and place it in the ear.

RINGWORM.

℞ Cupri oleate.....3ss.
Adipis benzoati.....3i.
M. Fiat unguent. Sig Use locally.

—*Shoemaker.*

MALARIA.

Sulphate of quinine.....grammes 12.
Sulphate of iron..... " 6.
Soft extract of cinchona..... " 15.

For ten pills, one every three hours; exercise in the open air; suitable nourishment. Paint with tincture of iodine the hepatic or splenic region.

FOR ASTHMA.

A medical friend advises the following formula, which I have found useful. I do not remember to have seen it in the text-books:

℞ Pot. iodidii.....3ij.
Fld. ext grindelia robusta.....3ij.
Fld. ext. belladonna.....gr. xxv.
Tr. gelsemium.....gr. xl.
Aquæ.....3j.
Elix. simpl.....ad 3vj.

M. Sig. One and a half teaspoonfuls every two or three hours until three doses are taken. Usually by the time the third dose is taken the tightness of breathing is gone.

—C. S. Gray, M. D., Little Rock, in *Jour. State Med. Society of Arkansas.*

HÆMORRHOIDS.

The following (*Il Raccoglitore Medico*, No. 16, 1891) is employed:

℞ Cocain. mur.....gramme 1.
Morph. sulph..... " 0.25.
Atropin. sulph..... " 0.20.
Tannin polocrizat..... " 1.
Vaselin.....grammes 36.

Mix well and carefully. Apply locally once or twice daily, and especially after an evacuation.

BICHROMATE OF POTASH IN HÆMATO-CHYLURIA.

Dr. Manuel Delfin (*Cronica medico-quirurgica de la Habana*, Tomo XVII, No. 17) has used the bichromate of potash with success in several cases of hæmato-chyluria. He used the following formula:

℞ Potassii bichromat.....cgms. 5.
Aquæ destillatæ.....grammes 250.

A teaspoonful on rising and at meal times.

The writer has no good theoretical reason for having used the remedy, but feels assured that in potassium bichromate we have a means of modifying that terrible disease, so difficult to successfully treat.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by postal note, money order or registered letter.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER; For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

LEADING ARTICLE.

THE TREATMENT OF PHTHISICAL COUGH.

The cough in phthisis is perhaps the most troublesome of all the symptoms we are called upon to treat. It cannot be said that all of the brilliant researches which have lately been made respecting the etiology and treatment of this disease have advanced our knowledge regarding the management of this distressing symptom. We must still rely upon only clinical experience, and until the rational treatment recently proposed has shown itself of positive value, the symptomatic treatment will remain of chief practical value to practitioners of medicine. In nearly every case of consumption this symptom cough calls for treatment, and it is very often one of the gravest questions possible how it shall be properly dealt with. Not only is it troublesome, annoying, and painful to the patient, but it causes vomiting, loss of sleep, hæmoptysis, pneumothorax and exhaustion when it is violent and prolonged. For practical purposes the cough in phthisis may be divided into two kinds: (1) ineffectual and feeble; (2) excessive. The very feeble, ineffectual cough is always a grave symptom when occurring in the later stages of consumption and associated with exhaustion and general debility.

J. Mitchell Bruce, M.A., M.D. L. R. C. P., who, from his large experience as a physician to Charing Cross Hospital, and to the Hospital for Consumption, Brompton, is entitled to his high reputation as a teacher, has delivered an excellent lecture upon this important subject (International Clinics, April, 1891, p. 43), in which he discusses the treatment of cough, under headings referring to the time of its occurrence, as follows:

(1) "Cough in the evening; (2) cough at bed-time; (3) cough during the night; (4) cough on waking, stirring, rising and dressing in the morning; (5) cough after meals; (6) excessive coughing any time, with or without abundant expectoration."

This division seems a practical and rational manner of discussing the subject, and as a

guide to the cause of the cough it commands itself as a routine method of thought. Cough in the evening may be due to the fatigue of the day and its consequent exhaustion, to over-heated rooms, tobacco smoke, bad air, or over-exertion on the part of the patient. The results are, as Bruce says, three-fold: "(1) Exhaustion; (2) rise of temperature; (3) cough." To prevent these and their bad effects upon the night's rest, the rational treatment of this symptom is to order such cases to retire early. Similarly, when cough at bedtime is a marked feature of any phthisical case it can very often be traced to sudden change of temperature, over-strain (going upstairs), etc., etc., and the most effective treatment will consist in the regulation of these bad conditions, and the strict avoidance of any of the causes which have been found to start the coughing. Should all the care possible in getting the patient upstairs and to bed fail to prevent the attack, Bruce recommends the giving of a few drops of the spirits of chloroform combined with a little lemon juice and simple mucilage, and if this fails, a small amount of morphine.

In cough occurring during the night, which is usually due to an accumulation of secretion, reflex irritability of the nervous system from fever and general exhaustion, he directs the use of warm food and stimulants, and that morphine should be withheld unless simple measures prove powerless to arrest the prolonged and useless attack; while for morning cough the indications are to refresh the system, to assist expectoration and to avoid all narcotics. These should be met by an early breakfast, hot drinks, or nourishing broths, which, by stimulating the strength and increasing the secretions, assist expectoration.

In dealing with "cough after meal" Bruce confesses that for such paroxsyms the only therapeutic indication is "to arrest the unhappy symptoms, an indication far too general to be of much service in the selection of a remedy." Cough at this time is very commonly attended by vomiting, and so nutrition rapidly fails. The main thing is to avoid large or habitual doses of narcotic sedatives, which very soon have a disastrous effect on the digestive functions, and sohasten the end.

Finally, Bruce discusses the control of violent cough occurring at any time, and advises the use of the following local measures, viz.: Swallowing of pounded ice, menthol inhalations, warm alum spray, morphine insufflations with double the quantity of powdered starch, inhalation of a few drops of chloroform on lint.

For "obstinate cough" Dr. Roland G. Curtin, of Philadelphia, who may justly be considered an American authority upon diseases of the chest, has brought to the notice of the profession the oil of sandalwood (Phila. Hosp. Reports, Vol. 1, 1890). Dr. Curtin thus summarizes his experience with this remedy in the wards of the Philadelphia Hospital and in private practice.

"In the first stage of phthisis the remedy acted in a very satisfactory manner, giving comfort and great relief to the patients when the cough was very troublesome. Sleep was prolonged and less disturbed and appetite was improved. In the second and third stages of phthisis, where the medicine was well received by the stomach, it added greatly to the comfort of the patient, greatly relieving the strain of coughing.

"In the cough of catarrhal pneumonia, it not only acted as an immediate quietant of the cough, but also in a number of cases it seemed to have a curative effect, the improvement being prompt and very decided. The profuse tenacious secretion was changed by liquefying it, which relieved the distressing symptoms, and it was finally diminished in quantity."

Dr. Curtin's claims regarding the value of sandalwood oil in the treatment of phthisical cough are based upon its local and general effects, as known to the profession all over the world in the treatment of urethritis, and the advantages which he points out from its use in preference to opiates are the immediate relief usually afforded, no impairment of appetite, unless it disagrees with the stomach (as it sometimes does), no constipating tendency, nor does the dose have to be increased after a while.

But the cough of phthisis is one which can never be treated by a set formula; each case must be dealt with according to the circumstances present. The value of hygienic measures cannot be over estimated, and the use of simple and rational means to the exclusion, as much as possible, of opiates, should always be adopted. In the future, it may be, we shall annihilate cough by directly attacking the cause of phthisis, but in the mean time we are dependent upon what bedside experience has taught us.

BOOK REVIEWS.

MICROSCOPICAL DIAGNOSIS OF TUBERCULOSIS. By Paul Paquin, M. D., late Professor of Microscopy, Bacteriology, etc., and Director of the Laboratory of Pathology, Medical Department, Missouri University, etc. Published by The Little Blue Book Co., Battle Creek, Mich. 24mo., 48 pp.

This little hand book has evidently been prepared with a view of affording those inexperienced in the study of the bacilli of tuberculosis the proper data to enable them to do such work readily, especially to put the means in the hands of the general practitioner by which many severe cases of consumption can easily be diagnosed.

The author refers very succinctly to the microscope and other instruments employed in the study of this kind of bacteria; the principle, object, and effect of staining; mounting; collecting sputum, etc.; staining fluids and their use; and various other interesting matters.

There are three handsome colored lithograph plates of the bacilli, besides a number of wood-cuts. It will be found a very useful manual.

AN INTRODUCTION TO HUMAN PHYSIOLOGY. By Augustus Waller, M. D., Lecturer on Physiology at St. Mary's Hospital Medical School, London; late External Examiner at the Victoria University. London and New York: Longmans, Green & Co. 1891. 8vo., 612 pp., 292 illustrations.

This is, on the whole, the most satisfactory text-book that has been published since the first appearance of the now classical work of Dr. Foster. Dr. Waller's presentation of the subject is particularly notable because of its brevity, clearness of expression, excellent style, originality, and absence of anatomical and histological details. While the author has been brief, he has not neglected that which should be found in a book of this character; nor can it be said on this account that the text is a mere summary of physiological data. The matter is not only presented with remarkable clearness, but with such originality and excellence of style, that the whole work has a distinct air of freshness.

The book bears evidence that the author is a careful and clear thinker, a thorough physiologist, and conscientious worker. It contains very few errors and omissions, it is well printed, and excellently illustrated, and altogether most admirable, and will undoubtedly meet with immediate and great success.

CORRESPONDENCE.

ANTISEPTIC FOR THE GRIPPE.

To the Editor of the Medical and Surgical Reporter:—The best antiseptic for influenza, or La Grippe, is sulphite of sodium, 5 grains, every two hours till all pain leaves the system. My prescription is:—

℞ Sodii Sulphit.....3iv.
Aq æ.....f3vi.
M. S.—A teaspoonful in as much water every two hours till all pain is relieved and the patient is well.

Yours truly,
J. A. Monell, M. D.,
New York City.

GLYCERINE FOR BURNS.

M. Grigoresen, of Bucharest, highly recommends pure glycerine as a remedy for burns. On first application a slight burning feeling is experienced, which soon gives away to a local anæsthesia, somewhat resembling that produced by carbolic acid. In severe cases two or three applications should be made, so that the parts are kept wet constantly with the glycerine. Under this treatment the inflammation is subdued almost completely, and only a slight cicatrix is usually left.

TO HASTEN DESQUAMATION IN SCARLATINA.

Dr. Jamieson (*Norsk Mag. for Lægevidenskaben*, No. 11, 1891) has employed 30 per cent of carbolic acid in oil with good results, but resorcine has served him better. This latter is combined with salicylic acid and employed in the form of a superfatted soap. The patients are anointed with this when desquamation begins; after this the skin is rubbed with some indifferent fatty substance. The nurse should wear rubber gloves to protect her hands. With these means the writer has shortened the period of desquamation from 55.5 to 40.26 days.

PERISCOPE.

MEDICINE.

THE RELATION OF FUNCTIONAL DISORDERS OF THE HEART TO DISEASES OF THE ABDOMINAL VISCERA.

Dr. Taylor, in his most interesting paper, in *The Practitioner*, draws attention to the association of cardiac derangements with abdominal visceral diseases, and records fifteen cases met with during the last four years.

The cases are divided into two clinical groups:

1. Violent and frequent action of the heart (palpitation, tachycardia, or heart-hurry).

Three cases are recorded:

Case 1.—Lady, past middle age. Paroxysmal attacks of violent palpitation, 260 and more beats per minute. Attacks of sudden onset, and would cease suddenly. They were excited by sudden noise, as slamming of a door, or any mental emotion, and a similar event would arrest the heart's gallop and reduce its action to normal frequency. A movable right kidney subsequently detected. Death occurred. No autopsy.

Case 2.—Lady. Paroxysmal attacks of violent palpitation, beats amounting to 200 per minute, and with tendency to alarming syncope. Attacks brought on by puff of wind or any such like trivial occurrence, but would cease suddenly without apparent cause. Patient had arrived at menopause, had frequent attacks of uterine hæmorrhage, and was found to have large uterine tumor with marked retroversion of uterus. Death occurred during an attack. No autopsy.

Case 3.—Male, aged 62. Paroxysmal attacks of violent heart-beating, sudden in onset and terminating suddenly, and unaccompanied by sufficient dyspnœa to cause real distress. Patient had an enlarged prostate, and presented symptoms of chronic cystitis. He was in the habit of using a flexible catheter. Death occurred apparently from surgical kidney, but rapid action of heart continued to the end. No autopsy.

Dr. Taylor also refers to a case mentioned by Dr. Bristowe, where the pulse ran up to 198 in a case of relapse in enteric fever; and after drawing attention to another case, also reported by Dr. Bristowe, where "when lying down, she [the patient] could arrest or prevent the palpitation by placing a cushion or pad under her loins, so arranged as to cause the back to be strongly arched," he pertinently asks, "Had this patient a movable kidney?"

The writer suggests that in these cases "a peripheral irritation of sympathetic nerves to the kidney, or to the uterus, or to the prostate and bladder, may be extended to the centres higher up in the cerebro-spinal nervous system, and thence reflected to accelerator nerves supplying the cardiac muscles."

Against the hypothesis that "the several organs of the body are showing signs of degenerative changes, and amongst them the heart, which is the first to attract our attention by reason of the urgency of its symptoms," it is very properly pointed out that cases of tachycardia not infrequently occur in early life or in persons who present no evidence of tissue decay.

2. Cases in which there is intermission or a decreased action amounting to marked slowness of pulse (bradycardia) with a tendency to syncope.

Twelve cases of this group noted. Seven have died. No autopsy.

Two cases of adult males, after enteric fever, where heart rate sank below 50, in one as low as 46.

One female child, aged 15, also after enteric fever where pulse rate of 54 noted.

Five men with chronic bladder and prostate mischief. Patients had first sought surgical advice for the urinary troubles, and then subsequently after the lapse of a few weeks or months symptoms of cardiac failure appeared.

Three cases, two men in prime of life and a woman of 45, with chronic bowel trouble and dysentery.

One woman, pregnant four months, in whom there also existed some uterine tumor, probably fibromatous.

After pointing out the effect injuries to, and operations on the abdominal cavity, have in producing a slowing of the pulse, it is suggested that possibly "lesions of abdominal organs produce upon the whole of the sympathetic ramifications, an effect which is far reaching in its consequences and which so influences the cardiac nerve-mechanism as to produce diminished activity together with lessened tissue repair." Should this be granted, the irregularity and intermission of the heart's stroke can readily be explained.

THE NERVE-SUPPLY OF THE INTESTINE.

Dr. Eskridge has recorded a case which he believes illustrates the nerve-supply of the intestine in the region of the ileo-cæcal valve. The patient was a man of thirty-three, who met with an accident to his back, causing, as was afterwards found, fracture and dislocation of the twelfth dorsal vertebra. Although he was in great pain immediately after the accident, and his back was very severely injured, he rapidly improved until the sixth day, when, after eating freely of boiled cabbage, he became sick, had coffee-ground vomit, and rapidly sank and died. At the necropsy it was found that the lower portion of the ileum and upper part of the colon were enormously distended and almost black in color. The distension extended from five inches above the valve to six inches below it, and at each end there was almost complete occlusion of the gut. The twelfth dorsal vertebra, as has been already mentioned, was found to be fractured and partially dislocated, and the twelfth thoracic ganglion of the sympathetic on each side was surrounded by inflammatory products and disorganized. This condition of the ganglia Dr. Eskridge regards as the cause of the distended bowel, and he attributes the constriction at either end of the distension to irritation of the tenth dorsal and first lumbar ganglia. Death he believes to have been due to internal hæmorrhage, resulting from irritation of the over-distended bowel.—*Lancet.*

THE BACILLUS OF CHOREA.

Berkley (*Johns Hopkins Hospital Reports*, Vol. II, No. 6) reports one case of chorea insaniens in a woman, and one of ordinary chorea in a dog, in which he has made most careful post-mortem examinations. He concludes his paper with these remarks: "It would seem that chorea might be considered as a general systemic affection, acting with greatest intensity on the vascular system and lepto-meninges, and that its cause is to be sought for in a special bacillus, or its toxical product, not a coccus, the staphylococcus aniens being only an accompaniment to the other germ, as in many other infectious diseases. The so-called "choreakörperchen" of Flechsig and Wollenberg are, so far as I am able to judge from the first writer's description, by no means peculiar to chorea; if I mistake not, they are to be found not only in the globus pallidus, but in other parts of the brain, not only in this affection, but also in normal as well as diseased brains.—*Univ. Med. Mag.*

FACIAL HEMIATROPHY.

The *Neurologisches Centralblatt*, No. 15, 1891, contains abstracts of several cases of facial hemiatrophy. The first is recorded by Borgherini (*La Psichiatria*, viii, fas. 3 and 4). The patient was a man, aged 63. He had had chronic inflammation of the right lachrymal gland, which was incised. Shortly afterwards he developed localized pain in the right orbit, creeping sensations, and a feeling of numbness in the adjacent skin, chronic contraction of the right forehead and face muscles, atrophy of the tissues on the right side of the face, and opacity of the cornea. This condition was, on the left, limited by the middle line of the face, and on the right by the anterior border of the temporal and masseter muscles. The second case is recorded by Muratow (*Vratch*, 1891, No. 25). It is that of a woman who sought advice on account of cramp in the muscles of mastication. This began on the right side, and had a clonic character at first, but soon became bilateral and tonic. There was atrophy of the right side of the face, affecting both the lips and the tongue. There were no electrical alterations in the muscles. There were several pigmented spots on the side of the face, and the skin had the appearance of scleroderma, but this condition had appeared before the cramp in the muscles. The third case is by Jankau (*Deut. med. Woch.*, 1891, No. 26). The patient, a girl, aged 22, had for two years noticed great pallor, with yellow pigmentation and atrophy of the right side of the face, extending over the distribution of all three branches of the trigeminus, and she had lost much hair on the affected side. About the time of the appearance of the hemiatrophy the patient began to suffer from enlargement of the thyroid and ozæna. The next case is recorded by Dixon (*Dublin Journ. of Med. Science*, February, 1891). In a boy, aged 11 years, there followed, upon a violent blow over the left hip, schleroderma of the left half of the body, the left side of the face, and the left extremities, with atrophy of the affected arm and

leg, hemiatrophy of the face, and alopecia of the left half of the body. The last paper is by Girard (*Revue Méd. de la Suisse Romande*, 1891, No. 6). He cut through the sonsory portion of the trigeminus in the skull in dogs, and this was followed by hemiatrophy of the face, atrophy of the muscles of mastication, thinning of the skin, atrophy of the bones and of the tongue on the same side. He, therefore, concludes that the trophic fibres for the face run in the trigeminus, and not in the facial nerve.—*Brit. Med. Jour.*

THERAPEUTICS.

THE HYPODERMIC INJECTION OF CAMPHOR.

The employment of camphor hypodermically in solution in oil, alcohol, or alcohol and ether, is more general on the Continent than in England. German and Russian practitioners esteem it a valuable method of treating symptoms of impending collapse. Dr. Alexander, of Berlin, has published a paper giving the results of an extensive series of observations made during the last two years on the effects of hypodermic injections of oleum camphoratum (composed of one part of camphor to nine parts of olive oil) in a large number of cases of disease of the lungs. The dose given was fifteen minims once a day. As the effects of camphor are cumulative, it was found that four daily injections were as much as could usually be borne without some unpleasant effect, such as headache and restlessness at night. After an interval of a week, however, one more injection could be given without causing any unpleasant symptoms. Phthisical patients seemed to bear continued treatment better than others, and its results in the last stage of phthisis were very valuable, the night-sweats, the irritating cough, and the expectoration being diminished in a remarkable manner, even the first dose effecting a very noticeable improvement in the patient's condition. In hæmoptysis the method also proved very useful, patients being enabled to get about again without any fear of a recurrence more rapidly than under ordinary methods. Camphor injections administered in bronchitis increased the secretion at first, and afterwards caused it almost to disappear. They did not seem to be of much use when there was also emphysema. In pneumonia their value was especially marked in weakly individuals or in those with cardiac disease, and they cut short follicular tonsillitis and acute coryza. It was found that in some cardiac cases, where digitalis had ceased to be of benefit, after a few camphor injections, it could be again given with good results. These injections must, of course, be given to children only in very small quantities, but no effect appeared to be produced on the infants of mothers who were being treated by camphor injections for catarrhal pneumonia.—*Berliner Klinische Wochenschrift.*

STRYCHNINE NO CURE FOR DRUNKENNESS.

Dr. Kleefeld, of Gorlitz, has tried hypodermics of strychnine for the cure of drunkenness in seven cases. From one sixtieth to one fifteenth of a grain of strychnine were administered daily for ten days. The results were altogether negative. Although in two cases the morning vomiting was increased, in no case was the desire for intoxicants diminished.—*Deut. Med. Woch.*

ACUTE RHEUMATISM CONFINED TO THE TEMPORO-MAXILLARY JOINT.

The *British Journal of Dental Science* reproduces a report by Dr. Gallipe, published in *Le Progrès Dentaire*, of a case of acute rheumatism confined to the temporo-maxillary joint. It occurred in a patient of rheumatic diathesis. The symptoms were swelling of the cheek on the right side, with redness and pain on pressure; mastication and talking were both painful, with exacerbations at times. Pressure over the temporo-maxillary joint caused sharp pain. The upper and lower wisdom-teeth on the same side felt as if raised in their sockets. There had been no toothache. Careful examination of these teeth revealed no decay. The diagnosis was made of an attack of acute rheumatism in the right temporo-maxillary joint, and the patient was put upon salicylate of soda and quinine, rapid recovery resulting. Dr. Gallipe considers that the feeling of raising in the teeth was due to an attack of rheumatism in the alveolo-dental membrane itself, or rheumatic periodontitis, rather than simply the extension of pain from the affected joint.—*Lancet.*

PENTAL: A NEW ANÆSTHETIC.

Pental is the new name applied by Prof. J. v. MERING to *Trimethylæthylen*, a product of amylen-hydrate heated with acids, and recommended by the distinguished clinician as a safe and effective anæsthetic. Pental is described, chemically, physically, and as to its possible utility, in the *Pharmac. Zeitung*, Oct. 7, 1891, and in the *Pharmac. Centralhalle*, Oct. 15, 1891. Both journals conservatively withhold endorsement of the product, basing apparent skepticism on the fact that chemically the body has long been known, and that analogous amylens (for instance, *iso-amylen*) were employed as anæsthetics almost forty years ago, but quickly discarded because found to be unsatisfactory and offensive, owing to their unpleasant odor.

So was cocaine well-known; yet who will deny that the discovery of its wonderful anæsthetic properties was a revelation to the medical world, and worked a revolution in treatment and practice which will forever distinguish the name of the discoverer, Dr. KOLLER, whose publication in August, 1884, was responsible for the present universal application of cocaine.

While Pental will probably not excite the same degree of interest as did cocaine, it is safe to assume—reckoning on the high character and recognized conservative authority of Prof. v. MERING—that this product will find valuable application. From reports already furnished, notably that of Prof. HOLLAENDER, of Halle a S. (*Therap. Monatshefte*, Oct., 1891), which was read before the Dental Section at the Convention of German Naturalists and Physicians, at Halle, this year, the new anæsthetic is shown to be suitable and efficient for minor surgical operations, and particularly in dentistry.

Pental (C_5H_{10}) occurs as a colorless liquid, of low specific gravity; its boiling point is 38° C.; it burns with an illuminating flame, and is readily inhaled without affecting the membranes of throat or passages. It is insoluble in water, but miscible in all proportions with alcohol, chloroform or ether, and being inflammable, like the latter, must be protected from possible ignition. It is exceedingly volatile, but does not decompose on exposure to air or light,

The inhalations are simply conducted, 10 to 25 cc. of the fluid sufficing, and narcosis ensues within 50 to 90 seconds (Dr. HOLLAEDNER), without influence on respiration or the action of the heart, and causing no unpleasant side or after-effects. From a careful consideration of Dr. HOLLAENDERS' report, a most favorable impression of the value of Pental is gathered, and we hope to supplement and confirm this by early additional original reports.—*New Remedies.*

A REMARKABLE COMPLICATION OF LUPUS.

DR. V. LESPINNE communicated to the Congress on Tuberculosis a paper dealing with a complication of an infective nature, but little known, occurring in cases of lupus vulgaris (*Mercredi Méd.*, September 2d, 1891.) He says that in some cases of this disease, especially in the variety known as lupus exedens, there suddenly appears a series of pathological phenomena of a general nature, suggesting the onset of some new disorder. It is especially when the patch of lupus is about to ulcerate that the complication supervenes, whether the ulceration be due to a natural cause or to surgical interference. A sudden rise of temperature commonly heralds the impending disturbance; the patient then falls into a condition of prostration, resembling the typhoid state. The mucous membranes become affected, there being general catarrh, with gastric disturbance and diarrhœa; the lungs also participate, a catarrhal condition of the bronchial tubes being revealed by the stethoscope. The serous membranes may also be involved; endocarditis appears, and a *bruit* becomes audible. The most striking feature of the disorder is the rapidity of its onset; the symptoms, moreover, appear almost simultaneously, so that a patient may present them all who was quite well the previous evening. Even when a lupus patch has cicatrized this general affection may supervene, in which case the scar breaks down and an ulcer forms. The condition of the patient resembles that seen in a case of typhoid fever or acute miliary tuberculosis, and the general disturbance recalls the results of the injection of tuberculin. It may be kue to the absorption of the products of pyogenic organisms, or of the products of the tubercle bacillus, or of the mixed products. The application of parasiticides and antiseptics to the lupus

patch is recommended. As regards the issue, in some cases the disturbance passes away entirely, and the patient regains his usual health; in others, general tuberculosis results. In cases in which the endocardium has been affected, the attack may leave the patient with organic diseases of the heart.—*British Medical Journal.*

NITROGLYCERINE SUBCUTANEOUSLY IN POISONING BY ILLUMINATING GAS.

Dr. Hoffmann (*Allgemeine med. Centr. Ztg.*, 1891; *Ugeskrift for Læger*, No. 27, 1891) reports a case of poisoning by illuminating gas where the patient breathed the air of a little room into which gas poured from an open burner from 11 in the evening until 9 in the morning. Four grammes (1 fl. ʒ) of ether were injected under the skin without result. One milligramme ($\frac{1}{60}$ gr.) of nitroglycerine was injected into the præcordial region. One-half a minute later the pulse became stronger and the respiration deeper. From then on the pulse was regular and strong. One hour later he could swallow several spoonfuls of coffee. That afternoon there was headache, dyspnœa and malaise. The next day he was entirely well.

SUBCUTANEOUS USE OF ERGOTIN.

Dr. Driver (*Therap. Monatsh.*, September, 1891), says that acute hæmoptysis coming on suddenly and due to erosion of large vessels, cannot be stopped by any injection of ergotin, but that the cessation is brought about by the coagulation of the blood in the cavity acting as a tampon. Absolute rest and the controlling of the cough by morphine are necessary. There is no object to be gained by the ice bag, and the inhalation of astringents is harmful. In cases of continued capiliary hæmorrhage from the walls of the cavity (which must be looked upon as due to a congestive hyperæmia), the author says that, combined with measures to increase the heart's action, ergotin is almost a sovereign remedy. The dose used is generally too small. If the bleeding is severe, 0.5 to 1.0 gram. should be given. After disinfecting the syringe, the required amount of ergotin (Bombelon) is taken up, and the syringe filled with distilled water or a very weak solution of carbolic acid or morphine. This is injected after the skin has been thoroughly cleansed. In this way no inflammation or suppuration will arise.—*British Med. Journal.*

SURGERY.

STAB-WOUNDS OF THE SPINAL CORD.

Dr. Otto Bode (*Berliner klinische Wochenschrift*, Jahrg. xxviii., No. 22) gives an interesting account of the diagnosis, course, and proper treatment of stab-wounds of the spinal cord. He cites the case of a man, who, in a street fight, received several wounds on the head; on the back of the neck there was one about five centimetres long, running obliquely down to the spinal column and exposing at its bottom the atlas and axis. At the moment of wounding the patient fell to the ground, lost consciousness for only a minute, but remained paralyzed on the right side below the point of wounding. When called upon the right lower extremity responded slowly and reluctantly, but for walking or standing was weak and useless. There were no areas of anæsthesia, nor any disturbance of the special senses. The bladder and rectum were normal; priapism not present. The muscles of respiration on the right side were decidedly implicated. The faradic excitability of the muscles remained normal. For three weeks this condition continued apparently unaltered. At the expirrtion of this time the patient began to gain more and more the use of the paralyzed limbs, albeit at the same time the reflexes became greatly exaggerated, and at the least touch the muscles jerked. The patient was under observation for three months; the paralysis was practically gone, and even the reflexes had returned to normal, and in a year's time no evil effects of the wound remained, save at times a slight tremor in the muscles which had been paralyzed. The wound was treated solely by the antiseptic dressings.

From the anatomical relations of the vertebræ and their ligaments, Dr. Bode proceeds to show that in the cervical region when the neck is bent down, as it usually is when a man receives a wound there in a fight, the cord can be wounded at almost any point of its circumference, or, indeed, may be wholly severed, without injury to the vertebræ. From the

motor disturbances and the direction of the external wound in his case, he diagnoses a partial severence of the anterior column and the anterior part of the lateral column on the right side. Therefore, he maintains that it is not possible that the lateral columns in the cervical cord carry both sensory and motor fibres, since in his case there were absolutely no disturbances of sensation.

Dr. Bode cites several cases of perfect healing of wounds of the spinal cord involving not quite half its diameter, which were recognized during life to be wounds of the cord, or were subsequently clearly demonstrated at the autopsy by the cicatrices.

He goes on to explain that the appearance of symptoms which set in generally on the second or third day after the wounding, and which might easily be mistaken for traumatic myelitis, is due to what Schiefferdecker describes ("Ueber Regeneration, Degeneration, und Architektur des Rückenmarks," *Virchow's Archiv*, Bd. lxii.) as traumatic degeneration following wounds of the spinal cord, and setting in on the second to the third day. The degeneration begins as a disintegration of the elements of the nerves into glossy flakes. This process extends from the cut surfaces about four to six millimetres above and below. Hence, in the case of wounds in the neighborhood of the fourth cervical vertebræ, although the phrenic nerve be not at first implicated, yet at the end of the second or third day that complication may arise.

The increase of the reflex excitability, Dr. Bode explains as due to what Schiefferdecker describes as secondary degeneration, which manifests itself about the fourteenth day, and which, by cutting off the influence of the reflex inhibitory fibres running down the lateral columns in the cervical cord, gives rise to an increase in the reflexes. Schiefferdecker describes a third form of degeneration, which he calls cavity formation, and to this Dr. Bode ascribes the fibrillary tremors in the limbs formerly paralyzed.

Retention of urine and fæces is not uncommon following wounds in this region. The organs either return to normal or else incontinence sets in. The height of the wound has no influence hereon. Priapism almost always occurs where there is vasomotor disturbance. Elevations of temperature are not found on the anæsthetic areas of the skin, if there be any, but only on the areas where there is motor paralysis. This proves that the vascular nerve-supply runs down the same paths as the motor fibres. Dr. Bode cites a very interesting case where he found variations of temperature of the affected part entirely independent of the temperature variations in the rest of the body.

He maintains that it is possible to locate with absolute certainty the position of the wound on the cord from the symptoms, since some hæmorrhage affecting the parts immediately adjoining is inevitable, and, furthermore, unless the assailant's knife be very sharp, it must make more or less of a contusion on the cord before it cuts through the elastic pia mater.

To sum up, the most conclusive symptom is a sharply defined paralysis below the point of wounding, coming on at the moment the wound is received.

As to treatment, he says, the external wound should be enlarged and left open. above all, free drainage should be encouraged, even to the loss of meningeal fluid, and the blood and secretions of the wound should be kept aseptic. Finally, the wound should be allowed to heal by granulations, or sewn up secondarily.—*Amer. Jour. Med. Sciences.*

PÆDIATRICS.

COMMON THYME IN WHOOPING-COUGH.

Common thyme, which was recommended in whooping-cough three or four years ago by Dr. S. B. Johnson, is regarded by Dr. Neovius, who writes a paper on the subject in a Finnish medical journal, as almost worthy of the title of a specific. During an epidemic of whooping-cough he had ample opportunities of observing its effects, and he came to the conclusion that if it is given early and constantly it invariably cuts short the disease in a fortnight, the symptoms generally vanishing in two or three days. They are liable to return if the thyme is not taken regularly for at least two or three weeks. He gives from one ounce and a half to six ounces per diem, combined with a little marshmallow syrup. It may produce a slight diarrhœa. It is important that the drug should be used quite fresh.—*Amer. Jour. Med. Science.*

ON VISCERAL HÆMORRHAGES IN STILL-BORN CHILDREN; AN ANALYSIS OF ONE HUNDRED AND THIRTY NECROPSIES.

Spencer (*The Lancet*, June 20, 1891), in a paper giving a detailed account of a consecutive series of one hundred and thirty necropsies, on fresh, mostly still-born fœtuses, discussed the causation of the hæmorrhage, and reached the following conclusions:

1. In children still-born, or dying shortly after birth, congestion or œdema, and hæmorrhages, are usually found in various important viscera.

2. These hæmorrhages occur in cases delivered either naturally or by version, or by forceps, through normal or abnormal pelves; in primiparæ and multiparæ; with large and small children; in "easy" and difficult, rapid and prolonged labors.

3. These hæmorrhages are, however, most frequent and severe in children subjected to much pressure by the parturient canal, or instruments, or the hand of the attendant, especially when delivered by the lower extremity.

4. Cerebral hæmorrhage is more frequently found in still-born children delivered by the forceps than in those born by the breech, and in these latter more frequently than in those born naturally by the head.

5. Hæmorrhage into most of the other viscera is more frequently met with in pelvic than in cephalic presentations.

6. These hæmorrhages and the accompanying injuries are in many cases the cause of still-birth, and when not immediately fatal may be followed by the gravest consequences.

7. They are most likely to be avoided by preventing premature rupture of the membranes, by artificial dilatation of the parturient canal (when necessary), by restricting the employment of version and other artificial manipulations to urgent cases, and by preferring cephalic to podalic version in cases suitable for the former.

8. The use of the forceps should be absolutely limited to cases in which there exists some pressing danger to mother or child, and it should never be employed merely to shorten the time of labor.

9. In breech presentations, examinations of the genital organs of the child should be carefully avoided during delivery. As soon as the child's limbs are born they should be wrapped in a thick layer of antiseptic wool. If traction be necessary it should be made over wool wrapped around the child's limbs or pelvis. It should never be made by the hand around the child's waist.

10. In delivering the after-coming head, care should be taken that the sterno-mastoid muscles are not unduly stretched or pressed upon. When the after-coming head is in the pelvis, where there is even slight difficulty, resort should be had to the forceps.

OBSTETRICS.

IS A CHILD VIABLE AT SIX AND A HALF MONTHS?

Dr. Llewellyn Elliot, in a paper read before the *Am. Assoc. Obstet.*, Sept. 18, 1891, reaches the following conclusions:

1. A child under peculiar circumstances of development is viable at four months.

2. A child is viable at six and a half months.

3. The moral character of the parents has nothing to do with the birth of a premature child, when considered from a standpoint of constitutional development.

4. Obstetricians should strive to convince jurists of these facts.

SEPTIC DISEASE OF THE UMBILICUS.

Eröss, from a study of the temperature of 1000 infants born in the obstetric clinic at Buda-Pesth, comes to the conclusion that septic infection from the navel in association with detachment of the umbilical cord is a frequent cause of fever, and an important element in the mortality of infants (*Wiener med. Woch.*, No. 41, 1891). Fever of longer or shorter duration was present in 450 cases, and in 220 it was due to a pathological condition at the umbilicus; gangrene of the cord in 81, sloughing in 55, protruding stump in 55, omphalitis in 24, ulceration in 3, and gangrene of the umbilicus in 2; death occurred in 8 cases. Waddington (*Journ. of the American Medical Association*, October 10th, 1891) reports two cases of tetanus neonatorum which began to recover immediately after the application of thorough antisepsis to the foul granulating protrusion at the umbilicus, combined with the internal administration of betanaphthol (gr. 1) and chloral hydrate

(gr. 1). He states that he had previously met with six other cases of the disease, all of which were fatal; these six cases had been treated by sedatives, and not by antiseptics.—*Brit. Med. Jour.*

SUBCUTANEOUS INJECTIONS OF ETHER IN PUERPERAL ECLAMPSIA.

An interesting supplement to the treatment of puerperal eclampsia is offered by Dr. Perron, and quoted in the *Wiener Med. Wach.*, April 12, 1891. The case recorded was that of primipara, twenty years old, who was seized with eclamptic convulsions two hours after delivery. Chloral in liberal doses, blood-letting, and even inhalations of chloroform, had been tried without avail. The convulsions, which had begun at eight in the morning, continued with unabating severity to return every half hour until noon, and then became almost unremitting. The patient lay convulsed with severe dyspnœa and deeply cyanosed, her breathing was labored and stertorous, and death was momentarily expected. Dr. Perrin then injected subcutaneously a syringeful of ether, and in a few minutes the respirations became more regular and less labored. Fifteen minutes later another similar injection was made, and a third injection two hours later. After the second injection the convulsions ceased entirely, and the patient made a speedy recovery. It is to be noted that no albumen was found in the urine.

INTRA-UTERINE IRRIGATION AFTER LABOR.

L. S. McMutry (*American Journal of Obstetrics*, October, 1891) speaks of the difficulty of treating post-partem sepsis in its initial stage. If the case has been subject to extensive laceration of the maternal parts, or one where frequent examinations and manipulations have been necessary after labor, or when the precautions against sepsis on the part of the physician or nurse have not been perfect, then an accession of fever on the third or fourth day, with fetid discharges, should indicate at once the necessity for intra-uterine irrigation. When the absorption of septic symptoms is marked by a rigor or pronounced chill, followed by high fever and tenderness above the pubes, systematic flushings of the uterine cavity by the surgeon should be practiced every two, four or six hours, as indicated by the character of the discharge. Antiseptic agents are not essential, but the decomposing material should be flushed out. Patient should be gently lifted on a table and placed in Sims' position, the speculum introduced and the uterus irrigated with warm water that has been previously oiled. The extremities of the patient should be protected by sufficient covering. In cases where manual detachment of the placenta has been necessary, the douche may be supplemented with the application of the dull curette or Simin's spoon.

GYNÆCOLOGY.

THE EARLY DIAGNOSIS OF CANCER OF THE UTERUS.

Winter (*Berliner klin. Wochenschrift*, 1891, No. 33) reviews the recent results of extirpation of the cancerous uterus in Germany, showing that the total mortality of the five principal operators is only 8 4 per cent., the lowest being Kaltenbach's (3.3 per cent.). Although a certain number of fatal cases is inevitable on account of the difficulty of absolutely eliminating sepsis, other dangers ought to be avoided by improved technique, so that the mortality can be reduced to 5 per cent. The statistics of high amputation are still better, the Berlin Klinik showing a mortality of 6.5 per cent. (in 155 cases) previous to 1884, since which time no deaths have followed the operation in 64 additional cases.

Unfortunately, the remote results of both operations have not been as favorable as could be desired. A local recurrence (in the cicatrix) can usually be expected within two years at the utmost, while recurrence in the lymph-glands and pelvic connective tissue occurs later, This difference has not been clearly defined in the statistics. According to the writer's observations, after high amputation, 38 per cent. of the patients were well at the end of two years, and 26.5 per cent. had no recurrence five years after operation, after which time a return of the disease is exceptional. Fritsch has noted 36 per cent. of cures after vaginal hysterectomy at the end of five years, and Hofmeier 33 per cent. at the end of four.

Only a small proportion of the patients with cancer of the uterus are suitable cases for a radical operation (about 25 per cent.), and if one-fourth of these are cured, it follows that only 7 per cent. of

the entire number of cancerous patients are cured. In other words, the diagnosis of malignant disease is not made at a sufficiently early stage, and this neglect is traceable to the general practitioner. "The physician to whom the patient first applies decides her fate in the majority of cases." Hence it is extremely important that he should be familiar with the initial symptoms. Of these a watery vaginal discharge is the most constant, especially in carcinoma of the portio. Mænorrhagia, in a patient whose flow has formerly been normal should always awaken suspicion and lead to an examination. Hæmorrhage after coitis is an initial symptom of great importance, and when occurring some time after the establishment of the menopause it is almost pathognomonic of malignant disease.

Pelvic pain is usually a late symptom, due to secondary parametritis; but intractable sciatica, developing after the menopause, is significant. When a patient with these symptoms applies to her physician she ought certainly to be examined, and if the portio does not present a suspicious appearance, search should be made for cancer higher up in the cervix or corpus uteri. Fragments should be removed for microscopical examination. Patients themselves are often to blame since they defer seeking professional advice until too late, because they have no severe pain, the irregular hæmorrhages being attributed to the approaching change of life. It is a peculiar fact that women who have cancer are less likely to fear it than those who have not. In conclusion, the writer urges that both physicians and patients should be trained to recognize the initial symptoms of cancer of the uterus, and to have the diagnosis settled at once.—*Am. Jour. Med. Science.*

PRIMARY CANCER OF THE CLITORIS.

Dr. F. J. Merkle (*Centralbl. f. Gynäk.* October 3d, 1891) observed this disease in a woman, aged 61. At the site of the clitoris was a tumor of about the size of an apple, already beginning to break down. There was an indurated gland as big as a walnut in the left groin. The tumor of the clitoris was removed by means of the thermo-cautery. The patient died seventy-three days after the growth was removed. At the necropsy, epithelioma of the clitoris, with metastatic deposits in the lymphatic glands, was discovered. Dr. Merkle believes that the clitoris was most probably the seat of the primary disease in this case.—*Brit. Med. Jour.*

HYGIENE.

VACCINATION AS A PROPHYLACTIC AGAINST INFLUENZA.

Goldschmidt (of Madeira) some time ago adduced evidence (*Berlin klin. Woch.*, November 19, 1890, that vaccination had a prophylactic influence as regards influenza. An epidemic of small-pox broke out in November, 1889, and rapidly extended over the island. In January, 1890, influenza made its appearance, the epidemic reaching its height in February and March, disappearing gradually in May. Just at the time it was becoming severe re-vaccination was being extensively practiced on account of the contemporaneous invasion of small-pox, and it was observed that all successfully re-vaccinated persons remained exempt from influenza. Goldschmidt observed 210 cases of re-vaccination, 112 being successful. Out of the 98 without result only 15 contracted influenza, and even these were very slight cases. In an isolated villa with 26 inmates, of whom 14 were not re-vaccinated, all the latter were attacked with influenza, in two cases very dangerously; while all those who had been re-vaccinated remained free. In a recent paper (*ibid.*, November 2, 1891) Goldschmidt compares the statistics of the German army for 1889 with others relating to the civil population. The former show that 55,263 men (11 per cent.) were attacked with influenza. Of these, 60 died, giving a mortality of about 0.1 per cent., or a death rate of 0.01 per cent. for the entire army. Of the men enrolled during 1889, 85 per cent. were vaccinated with, and 15 per cent without, result. Assuming the same proportion for the whole service, there would be 75,900 men re-vaccinated without result, a number much larger than that of the influenza cases. Berlin showed a death-rate from influenza of 0.12 per cent. of its civil population (1.875 deaths), and Paris one of 0.25 per cent. (5,630 deaths); while that for the German army (0.01 per cent.) amounted to only one-twelfth of that for Berlin, and one-twenty-fifth of that for Paris. This result repeats itself with but slight vari-

ation for all other German and non-German towns. The relative proportion of influenza cases to population must, therefore, have been much greater for these towns than for the army, and their mortality must also have been greater, since that for the army (0.1 per cent.), if applied to Berlin, with its 1,875 deaths, and to Paris, with its 5,630 deaths, would indicate a larger number of influenza cases than their actual populations. From the most trustworthy sources a mortality of 0.3 for Berlin, and one of 0.4 for Paris, may be assumed as not far from the truth. These numbers would indicate an extent for the epidemic of 40 per cent. and 62 per cent. of the populations of Berlin and Paris respectively, as compared with 11 per cent for the German army. A number of garrisons remained quite exempt, even where there was no isolation, while the civilians suffered severely. Goldschmidt considers that the relative immunity conferred by vaccination is probably not lasting.—*Brit. Med. Jour.*

ARE COLDS INFECTIOUS?

The question of whether catarrhal attacks, popularly known as "colds," are infectious, is often debated in family households, and although no definite investigation in the direction of ascertaining the presence or not of a specific germ in the mucous discharges has been undertaken by bacteriologists, there is still strong presumptive evidence that infectivity of some sort prevails in these cases. The subject is discussed by Mr. Hutchinson in the last number of his *Archives*. He remarks that "colds" are capable of origination by influences brought to bear on the nervous system, and their secretions become infectious. "Thus many being from exposure to draughts or damp, and many others from personal infection. No distinction is to be drawn between the two; they are, as a rule, exactly alike. Those which arise from infection, may, however, be developed into special virulence, and may then prevail as epidemics, which are attended by more or less individuality of type. Probably infection is the cause of by far the greater number of common colds. Infection may be believed to be always at work when a cold goes through the family." Some day, perhaps, a catarrhal bacillus will be discovered. Under any circumstances researches in this direction would probably be productive of interest to the bacteriologist, and, moreover, from the information so gained, the possibility is not a remote one that some definite treatment could be designed for the alleviation of one of the most annoying morbid affections to which we are subjected at this period of the year.—*Medical Press.*

MEDICAL CHEMISTRY.

A COLOR REACTION FOR SALOL.

A few drops of nitro-sulphuric acid are put into a watch-glass and a few grains of powdered salol sprinkled in. This is colored yellow, and on stirring with a glass rod the color passes from brown to green. As soon as this tint is seen the contents of the watch-glass are transferred to a porcelain dish, 50 ccm. of water added and well stirred, the liquid becoming rose-colored, while the green tint may be restored by the addition of ammonia. Resorcin treated in the same manner becomes at once of a deep blue color; on adding water a red coloration is given, which ammonia changes again to blue.—*Journ. de Pharm. d'Anvers.*

THE COMPOSITION OF TUBERCULIN.

Klebs (*Deutsche medicinische Wochenschrift*, Nov. 5, 1891) records some further experiments confirmatory of the view that the injurious effects produced upon patients by tuberculin are due to non-essential ingredients, which can be removed without affecting its potency. These ingredients he believes to be organic bases (alkaloids), giving the well-known reaction of alkaloids, and which Klebs originally separated by precipitating tuberculin with absolute alcohol and extracting with benzol and chloroform. By this means was obtained a substance called *tuberculinum depuratum*, which gives but faint alkaloid reactions, but which, equally with the ordinary tuberculin, is able to cure animals suffering from tuberculosis. Recently Klebs has improved on this method, and a full description of the details will shortly be published. In the preliminary sketch, now published, he states that he has called the new product *tuberculocidin*, on account of its power to kill the tubercle bacilli. The mode of preparation consists in the separation of the alkaloids, and the extraction of the tuberculocidin from the precipitate by water. The properties of this newly-discovered tuber-

culocidin are precipitability by absolute alcohol and ammonium sulphate, its behavior towards the albumen tests, and its physiological action. This substance is entirely innocuous, causing no rise of temperature and rapidly improving the condition of tuberculous patients. The hectic fever and the night sweats disappear; appetite improves, body weight increases; all the signs of pulmonary catarrh rapidly clear up. Thirty such cases have already been treated by it, without any ill effects whatsoever. More time for observation, however, will be required before the patients can be pronounced absolutely cured.—*Brit. Med. Jour.*

NEWS AND MISCELLANY.

STATUS OF THE MEDICAL PROFESSION IN JAPAN.

It appears by the latest census returns made up to the end of 1889, the total number of physicians was 41,405, being an increase of 465 as compared with the the previous year, The total number of apothecaries, midwives, and druggists was 32,111, being an increase of 1,257 as compared with the previous year. The number of hospitals was 573 at the end of 1889 public hospitals had decreased by 3, while private hospitals had increased by 12, as compared with the previous year. From the same source we gather that the relative proportion of the medical profession to that of the population is much greater in Japan as compared with England. The actual ratio of population to each medical practitioner being 965.—*Med. Press*

INTERNATIONAL DERMATOLOGICAL CONGRESS.

The Second International Congress of Dermatology will be held at Vienna from September 5 to 10, 1892. Professor Kaposi is President of the Organizing Committee. The following subjects are proposed for discussion: The Lymphatic Diseases of the Skin from the Anatomico-pathological Point of View, to be introduced by Dr. R. Paltauf, of Vienna; the Present Condition of Leprosy in Europe, by Drs. Arning, of Hamburg, and Petersen, of St. Petersburg; Dermatomy-coses with Special Reference to the State of Affairs in France, by Dr. Feulard, of Paris; Late Syphilis, by Professor Neumann; Anatomy and Development of Epidermic Pigment, by Professor Jarisch, of Innsbruck; Psorospermosis, by Professors Neisser, of Breslau, and C. Boeck, of Christiania; The Principles of the Treatment of Gonorrhœa, by Professor Neisser; Lupus Erythematosus, by Mr. Malcolm Morris, of London, Dr. Th. Veiel, of Canstatt. Addresses will also be delivered by Drs. Besnier and Fournier, of Paris; Pick, of Prague; Doutrelepont, of Bonn; Schwimmer, of Buda-Pesth; and Riehl, of Vienna. In connection with the Congress there will be an Exhibition illustrative of the pathology and treatment of skin diseases and syphilis. Communications relative to the exhibition should be addressed to Dr. Hans Heger, I, Stefansplatz, 8A, Vienna. The General Secretary of the Congress is Docent Dr. G. Riehl, I-20, Bellariastrasse, Vienna.

THE CHARACTERISTICS OF THE PRESENT PANDEMIC OF INFLUENZA.

According to observations made at recent meetings of the Berlin Medical Society, it would seem that the epidemic of influenza began there during the first week of November, the earliest cases admitted into hospital having come under treatment on November 7. Ruhemann stated that the most noticeable difference between this and the other recent epidemics has been the large number of women and children, and the small number of outdoor workers attacked. Guttmann mentioned an instance in which the admission of a single patient suffering from influenza was shortly followed by the occurrence of 13 fresh cases. Fränkel, who took notes of 138 cases, found that only 9 (6.5 per cent.) had suffered from the disease before. The chief complications have been pneumonia and heart failure. The effect on the death-rate in Berlin has not been so marked as during the last epidemic, but it has been considerable (27 per mille as compared with an average of 18). In other parts of Germany the effect has been more marked; thus official statistics show that the death-rate has been doubled, or nearly double, in several towns. It rose, for instance, to 44 in Posen (average 21), to 45.6 in Frankfort-on-Oder (average 23.2), in Bremen to 34.3 (average 17.1), and in Rostock to 33.5 (average 15.6)—*Brit. Med. Jour.*

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

CLINICAL LECTURE.

ABSCESSES OF THE BREAST.*

By PROFESSOR DUPLAY,
PARIS, FRANCE.

Gentlemen: I will to-day call your attention to a woman, 28 years of age, servant by occupation, delivered five weeks ago, who has suckled her child for seventeen days. She is now suffering from fissured nipples. After a little while she ceased nourishing the child at the right breast, because this had become tumefied and painful. On the 2d of June there appeared on the external portion of the areola a little abscess, near which there was a cicatrix, accompanied with a slight local induration. In five days the whole of the right breast became swollen and painful, and the patient decided to enter the hospital for treatment. The woman exhibits now an induration of the whole right mammary gland, but there is no invasion of the subcutaneous cellular tissue. There is no pronounced tension of the skin, nor are there any signs of fluctuation. Soon afterwards the consistency of the whole region became notably diminished; at the same time, there appeared a point within the nipple that gave distinct fluctuation. On pressing the gland, especially on this part, there is ejected, by the galactophorous ducts, a liquid resembling milk mixed with pus. Otherwise the patient is in a fair condition, and there is no marked abnormal temperature.

In the presence of these phenomena there is no doubt that we are here dealing with one of those varieties of phlegmasias of the mammary region, called "abscess of the breast;" but, thus formulated, the diagnosis is incomplete. It will be interesting to examine the case from etiological and anatomical points of view. There exists, indeed, a certain number of abscesses of the mammary region: Those of the nipple, those of the areola, and those of the mammary gland proper. The first ones are acuminate and globular. Velpeau calls them tuberous or tubercular. Our patient has neither of these abscesses. At the mammary gland proper we find superficial abscesses, deep abscesses developed in the cellular sub-mammary tissue, and abscesses of the glandular tissue itself. In our case, we have not, evidently, a superficial abscess; and I have asked myself, on the contrary, if we could not have an abscess belonging to this variety in another patient, delivered in our wards, in whom it was found, on the region of the breast, a limited fluctuating tumor, situated manifestly in the sub-cutaneous tissue; but here also the whole of the mammary gland is involved, and there is noticed a marked induration. The abscess, although superficial, came on as a secondary manifestation. The woman whose history I have given you at the beginning of this lecture, has no longer a sub-mammary abscess. This, in fact, is easy to diagnose with precision. It is projecting, giving rise to an extreme tension of the skin, and to a considerable swelling of the gland, all of which are characteristic signs. The question arises whether the condition is that of a parenchymatous abscess, a true mastitis, or a mammitis. In fact, what characterize a glandular abscess are the freedom of the sub-cutaneous cellular tissue, the mobility of the indurated gland in the deep parts, and the special consistency of the gland, as if it were injected with suet.

Let us study the pathogenic relations of the diagnosis. You know that the mammary phlegmons are especially frequent after labor, and they are also seen during the period of gestation. It is to-day proven that they are particularly common in women who, after they have suckled their children for a certain period of time, a few days or a few weeks, cease to do so. Our patient may be included among these, and I have told you that she

* A lecture delivered at "L'Hospital de la Charite," and published in *Le Progres Medical.*

suckled her own child for seventeen days before she sent it to a wet nurse. The effect of cold, the want of proper cleanliness, and the small sores produced by the mouth of the child, all play an important part in their production. They similarly occur, and with great frequency, if the sores about the nipples already exist at the time when the child begins to suckle, and which may be attended by a complete detachment of the nipples. All this constitutes a starting point for all causes of infection, and is, in a general way, the ordinary beginning of puerperal mammitis.

The pathogenic theories promulgated in regard to these affections have been modified. Velpeau still inclines to the theory that engorgement of the milk produces a painful distention of the galactophorous ducts, which finally rupture, and the milk, thus escaping and diffusing in the cellular tissue, is transformed into pus. It is scarcely thirty years ago when Sappey, Nelaton, and his pupil, Richard, opposed this old doctrine. They thought that the majority of the abscesses of the breast were the result of a lymphangitis, which, starting from the nipple fissures, rapidly gained access to the deep parts. This theory is somewhat seductive, and the anatomical reasons upon which it is based seem to carry a certain degree of conviction. The clinical proofs are far from being conclusive. I have often, with these alone, combatted the hypothesis of Nelaton, and I have done this based precisely upon a certain number of clinical facts: The nearly constant absence from the beginning of involvement of axillary glands in abscesses of the breast, whereas in other parts the least lymphangitis is accompanied by adenitis, oftentimes of a more serious nature than the original lymphangitis; then, the nearly always insiduous beginning of the mammary abscesses is strikingly different from the commencement of a lymphangitis, which is generally accompanied with rigors and high temperature. In one word, I am sustained by what we know about abscesses of other glands, such as the parotid and the testicle, in which the inflammation gains access through Steno's duct and vas deferens respectively. From these considerations I conclude that it is useless, in the case of the mammary gland, to seek for anything especial, and that the inflamation in this case must likewise travel through the glandular ducts, and invade, secondarily, the cellular tissue.

In these latter times the microbian doctrines have wrought serious changes in regard to this theory. I can understand how, instead of travelling through the lymphatics, the infection may be carried through the grandular tissue. However, this is not merely a theoretical view taken of the matter. Shosser has discovered and described microbes, all over the mammary gland up to the acini. Budin has met with an extremely rare form of mammary abscesses, and the one found in the woman before us may be an example of them: In three patients, on pressing upon the breasts, there was exuded from a galactophorous duct, not milk, but thick pus sufficient to fill a small glass.

He cites likewise one case of this nature, in which a complete cure was effected by this simple mauœuvre. The abscess, undoubtedly, had been developed from the very beginning solely upon the glandular elements. It was an abscess due to staphylococci. Cazin and myself have been conducting, of late, a series of bacteriological researches upon abscesses of the breast, and we have found either staphylococci or streptococci, but never pneumococci, which we expected to find in some cases, at least, in which their presence might have been accounted for by infection through the saliva of the child. Be this as it may, we must admit to-day that in the majority of cases, a microbian agent penetrates into the galactophorous ducts through the fissures of the nipples, or in some other way, as in the case of Budin, and that, secondarily, it invades the cellular tissue.

You will meet every now and then with a typical mammary lymphangitis, but the infection here follows a distinct and especial course. I believe that lymphangitis is frequently complicated, in the course of its development, with inflammation of the ducts; this may be the case with our patient, and we find considerable enlargement of the axillary glands, which are painless to the touch. What is the clinical history of mammary infections? Often they get well spontaneously, but always there is more or less formation of pus. The inflammation may be propagated to the subcutaneous, or deep cellular tissue, more frequently to the interlobular tissue, which becomes the seat of one or more abscesses, coming on simultaneously or successively, and converting the whole gland into a sponge of pus. Sometimes the pus gains access to the milk ducts; this is the form described by Budin, pointed out by Chassaignac, but which I do not consider as absolutely rare.

The prognosis of mammary abscesses is generally benign. Their formation, their rupture, and their cure may occupy but a few days. This is what is occurring in our present case. In other instances the affec-

tion assumes, on the contrary, a more serious character; fistulæ may be formed everywhere in the gland. These intermediary forms are the most frequent.

What is to be done in a mammary infection? At the beginning, compression, the refrigerants largely employed in Germany, topical applications (mercurial ointment), and antiseptic poultices may be tried; but I have little confidence in these measures. On the appearance of fluctuation I have always practiced incision. You know my manner of acting in these cases, which is contrary to the method of Gosslein, who recommends this procedure only as a last resource, or when an opening is established by itself. Erysipelas may come on as a complication from the presence of wounds; to-day we must fear, above all, purulent infiltrations, which may traverse and destroy the whole gland. In such cases, counter-openings may be necessary. You must not lose time if unfortunately a patient should come to you in the last stages of the disease, when not only abscesses, but even fistulæ may be present.

I will conclude by considering a practical point. After a cure has been established, the gland does not soon acquire its normal consistency; it continues to present an indurated or hardened condition even for weeks, although rarely this soon passes off. Most commonly a chronic mammitis is slowly developed towards the establishment of a complete cure. It is in these conditions you will obtain the best results from the employment of a methodical compression.

DUBOISINE AS A SEDATIVE AND HYPNOTIC.

Dr. H. Gellhorn recommends duboisine sulphate as a prompt sedative, having no dangerous by-effects, in the excitations of psychoses.

The hypnotic action of duboisine sulphate in simple agrypnia has not yet been fully gauged; perhaps sulphonal is prompter in this respect. In excited patients duboisine sulphate generally induces sleep. For these, according to Gellhorn, the dosage is as follows:

Hypodermically, 0.0008—0.0012 gramme ($\frac{1}{80}$—$\frac{1}{50}$ grain) per day, at one injection, for females; and 0.0012–0.0022 gramme ($\frac{1}{50}$—$\frac{1}{30}$ grain) for males. Internally, 0.0008–0.022 gramme ($\frac{1}{80}$—$\frac{1}{30}$ grain). In continued use the dose must must be increased slowly.—*Merck's Bulletin.*

THE PATHOLOGY OF HIP-JOINT DISEASE, WITH ILLUSTRATIVE CASES.*

By H. AUGUSTUS WILSON, M. D.

CLINICAL LECTURER ON ORTHOPŒDIC SURGERY, JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

Gentlemen:—Permit me first to draw your attention to the names that are given to designate a disease that we have studied in part, and one which we intend to study still more thoroughly, as we have illustrative cases to present before you. These names must be familiar to you, so that you may understand the conditions that are meant when they are mentioned. They are

Hip-joint disease,
Morbus coxarius,
Morbus coxæ,
Coxalgia,
Chronic articular ostitis of the hip,
Coxo-tuberculose.

If one man tells you that he saw a case of coxalgia, and another a case of morbus coxarius, and another a case of morbus coxæ, you must understand that the same condition is meant. The names have been ascribed by various writers to indicate what they thought was the nature of the disease. I prefer the simplest name possible to describe a disease. "Smith's disease," or "Bright's disease," do not indicate the true condition which is present, and especially is this true of the so-called "Bright's disease." How singularly does this term fail to convey to the mind the various pathological processes, which are grouped under that heading, as a deserved compliment to the investigator and profound student! I prefer the name "hip-joint disease," because it tells us it is a disease involving the hip-joint. You can be more precise, and call it "chronic articular ostitis of the hip," but you should call a disease preferably by the fewest words, and the simplest, and, if possible, by English words. So as to impress you more thoroughly with this disease, I will enter into a consideration of it in a manner directly opposite to the usual method of showing, first, the simpler, and then the graver forms of the disease, and finally the results. I will show you first the results, so as to impress upon you the necessity, as far as is possible, of preventing the condition which will, if neglected, result so disastrously. While I draw your attention to these names of the disease, you must remember

* Delivered at the Jefferson Medical College Hospital.

that they are but the slightest indication of the serious character, as results of failure to make early diagnosis and the application of remedial measures too late to be effective, of the cases which I shall bring before you.

The cases I present to-day show multiple deposits of tubercular bacilli in the bones. The little girl I showed you at our last lecture suffered from tubercular deposits in the soft tissues. This boy comes to us as a case of tubercular caries of the spine in the lumbar region; subsequently he developed on the right side a tubercular hip disease. It is not unusual for these conditions to be present in the same patient, for multiple deposits of tubercular tissue are frequently observed; thus there may be phthisis and a hip-joint disease in the same patient. This boy presents an illustration of the unfortunate results of this disease. Just in front of Pupart's ligament there is a sinus, which is the characteristic tubercular sinus, having the clearly punched hole. Around this are unhealthy granulations, the entire surface being covered with an ichorous, unhealthy pus of a greenish tint, the color of pus coming from a tuberculous caries. This sinus undoubtedly leads to an abscess and dead bone. As far as we are able to obtain the history of this patient, the opening occurred spontaneously, and the sinus will remain open as long as the diseased tissue remains, or until there are efforts made to eradicate the carious bone. Upon the side of the thigh there is a long cicatrix, and in the gluteal region we find another sinus. The long cicatrix followed an attempt at excision of the head of the femur. As to whether the operation was a success or not, I have merely to mention the fact that pus is exuding from the sinuses. These sinuses are indicative of a breaking down of the bone tissue, and do not prove by any means that an inappropriate operation has been performed. The extensive character of the infection rendered it impossible to remove all unhealthy structure at the time of the operation without serious and unwarranted risk to the patient. By an inappropriate operation, I mean an operation which was attempted to be performed, but was from necessity not thoroughly satisfactory in accomplishing the desired result. Thus, an excision of the head of the femur would be inappropriate when a large part of the ilium was diseased, the removal of which would be impossible. The marked difference in the calibre of the legs is due to an atrophy of all the muscles from their disuse. You will notice that in moving the boy, the pus wells out from all the sinuses, showing that the tissues are full. The marvel is that the boy is in his present good condition. The constitution stands the strain far better than you could imagine, but we must bear in mind in the analogous cases of consumption how patient and hopeful such patients are often for years.

HIP DISEASE WITH MULTIPLE SINUSES.

The next child was before you for a few moments at our last clinic, and I bring him before you now to emphasize some points I am desirous that you should understand. This patient is a chronic runner from one hospital to another. He stays at one place long enough to begin at improvement, and then starts anew at another place, where his mother has heard that a brighter prospect exists for his recovery. He has a tubercular deposit in his right hip-joint. There is a long cicatrix anteriorly, which was made some years ago, when a large abscess was opened and cleansed, but no dead bone found. Subsequently an opening on the outer side of the leg below the trochanters occurred spontaneously, discharging an excessive accumulation of pus from the hip. The entire leg was œdematous at the time, in fact almost erysipelatous. Quite recently, upon his entering the hospital, we endeavored by conservative means to accomplish a closure of the sinuses. We did this by means of the iodoform emulsion, and the sinus, as a result, is now almost closed, with no discharge of pus; but I see now, for the first time, a fresh swelling and redness on the inner side of the thigh, indicating a fresh deposit of tuberculous pus. I wish you to bear this case in mind as an illustration of the fact that we will not get the brilliant results in an excision of the tubercular joints that are obtained in much of the other surgery of the present day, and the explanation is that tubercular deposits are often submitted to operative procedure at too late a stage of their progress when complete removal is impossible.

I consider it a matter of the greatest importance that you see the results which so frequently follow this disease, in order that you may understand the reason for the stages of the procedure which I shall give you in detail later. The next case is a most profound example of the results which follow surgical attempts too late to be effective. The boy, as you see, comes in on a crutch and a cane, smiling, and yet he possesses a leg which has been a source of great anxiety to the surgeons who have treated him, as to know just what to do for him. Three years ago he presented himself with several sinuses around the joint,

and pus exuding to such an extent that the radical operation of excision was performed. The head, neck and trochanters were removed, and the parts healed well. Subsequently other sinuses appeared, and the entire wound became a tuberculous mass. These sinuses extended to the lumbar region and appeared all around the joint. At present there is a slight amount of exudation of broken down tissue. Shortening has resulted and you see here a result which is not pictured in the books. This case case shows what may take place, and always does take place, when the operation for excision is performed too late to achieve the desired purpose. There is a sinus anterior to the site of the greater trochanter, and one within near the groin, which is still running. The atrophy and shortening are marked. As the boy stands on his healthy leg he is able to swing the diseased limb to quite a considerable degree, but you will observe that the motion is not of the hip-joint, but at a compensating point in the lumbar region. Nature's efforts are to supplement a destroyed joint by providing another joint which will supply the motion lost by the disease in the joint.

PATHOLOGY OF HIP DISEASE.

Now then, gentlemen, what have we seen? We have seen something by name, let us get a clear idea what the name implies. I do not know how far I am teaching the views of the professors of surgery, but I am endeavoring to teach the modern views of the pathology of these cases. I am opening myself to criticism, I know, when I make the statement that in 95 per cent. of the cases, coxalgia begins in the ephthyses of the head of the femur. Some teach that the origin is in a synovitis; others that it is in the ligaments, and others that it is in the cartilages or in the ligamentum teres. During the last ten years under the methods of aseptic surgery it has become possible to perform operations which have hitherto been impossible. Up to that time and instead of being able to study the pathology of hip disease in its initial stages, we have been compelled to study results, and, by analogy, trace back the condition to the original cause. During the past ten years, however, surgeons have removed the head of the bone in the incipient stages. They have removed the head on the first indication of any serious lesion of the hip, and have found that in a very large proportion the disease began as an ostitis in the epiphyses of the head of the femur. This is a matter of positive fact, so we may lay aside as less important the theory that it can occu r in the tendons, the synovial membrane and the cartilages.

The osseous origin of hip-joint disease is advocated by Gross, Annondale, Marsh, König, Gibney, Volkmann, Bryant, Barwell, Bradford and others, while Sayre and Billroth are among those who teach synovial origin, and the ligamentous origin is favored by Owen, Holmes and Adams.

In sixty-one excisions of the hip performed by Muller, the osseous origin was determined in forty-seven, and synovial membrane in three, while it was impossible to tell accurately in eleven.

Since the discovery of the bacillus tuberculosus by Koch, are cognized change has occurred in the pathology, and now it is becoming an accepted fact that in the very large proportion of cases, the primary origin is in the form of an ostitis. Around the Haversian canals through which nutrient blood vessels pass, there are lacunæ seen under a 1200 diameter microscope, and from these lacunæ, caniliculi run out in every direction, communicating with each other and with the Haversian canals. The nutrient material of the bone comes from the perivascular lymphatics in the central canal and through the caniliculi from one lacuna to another. The Haversian canals become dilated and absorption of bone takes place and the surrounding bone tissue becomes spongy.

The Haversian canals become obliterated in chronic inflammation by deposition of inflammatory deposits, and often the bone becomes very hard and much thicker. In tubercular infection, the deposition of the bacilli takes place in the lacunæ and caniliculi; the bone becomes spongy and there is an increased tendency to degeneration. The process is hyperæmia, infiltration, absorption of trabeculæ and the formation of the enlarged spaces or cavities which become filled with cheesy matter.

Up to this point the progress of the disease is so insidious and the external manifestations so imperfectly marked that discernment is always difficult and often impossible.

From this condition, one of three courses are possible. First, the diseased process may be absorbed, and evidence of this having occurred has been found in pathological specimens.

Secondly, the growth of the deposit may take place towards the periphery, rupture through the periosteum and evacuate itself outside the bone, and be either absorbed from that situation or spontaneously open

through the skin. The latter is often prevented by a timely incision, and the sinus which is apt to be a result of spontaneous opening is thereby avoided.

The third possible course is, I believe, the most common, and gives rise to all of the symptoms and conditions known as the incipient stage of hip disease, namely, rupture of the tubercular ostitis into the joint cavity, thereby affecting that serous tissue with a purulent synovitis.

In proof of the fact that the disease usually occurs in the epiphyses, I wish to show you some specimens of excised heads of femurs. In the first specimen, I ask you to observe with great care that the rotundity of the head is destroyed, and that on the great trochanter the cancerous tissue is seen, showing that at the outset of the disease there was a disease of the bone necessitating the operation. In the second specimen the entire head and neck have been destroyed. An anatomist could scarcely tell what this bone is. The extensive inflammation has also invaded the trochanters. This third specimen, which was removed in adult life, goes just a step further; it shows a smooth head, proving that there was no serious inflammation of the synovial membrane. Just within the head of the bone you will observe this pocket where the original disease existed, rupturing into the joint. Excision took place prior to serious joint invasion with a happy result.

The progress of the pathological changes after a purulent synovitis has been set up are thickening of the capsule, infiltration of the periarticular tissues, thickening of the end of the bone, and formation of abscess. At this point the articular surfaces becomes eroded, and spontaneous luxation takes place, and if the case is untreated, cold abcesses continue to discharge through sinuses, which some times spontaneously close, only for new ones to form. The worst feature is that of which I have already shown you illustrations, namely, the dissemination of general tuberculosis, not infrequently life being terminated by tubercular meningitis.

Thus you will see the great importance of an early recognition of a disease which can be so successfully treated in its incipiency, but which is sure to produce most disastrous conditions if neglected.

I have purposely urged you to study hip-joint disease in the way we have done, so that I might this morning rivet your attention upon the care which is necessary in dealing with the incipient stage of the disease. The *incipient stage* is that period in which the first symptoms of the disease are present. The disease may be, and often is, present long before we are able to discern it by any known methods. It may exist as ostitis for weeks and months without our knowledge, and only be manifested when a synovitis develops itself. The earlier immobilization is applied to hip-joint disease the better will be the result. The truth of this assertion may be seen in those cases which have been allowed to run along, without early immobilization. I believe that in cases where a reasonable doubt exists in the diagnosis that it is judicious to resort to immobilization and await the developement of a certainty rather than to adopt the more common plan of letting the disease develop into a stage that renders successful treatment far more difficult. There is rarely any difficulty in diagnosis when decided purulent synovitis is present, and no credit is due to the one who then recognizes the lesion. The real difficulty lies in perceiving the character of the malady at the earliest possible moment. I believe that sensible parents will esteem you far more highly if you adopt the plan I refer to than to try to conceal your inability or the impossibility to make a diagnosis by recourse to statements that it is only growing pains, sprains, inflammation of the knee-joint, or other statements intended to be soothing. The full development of the disease, notwithstanding the comforting assurances, will be sure to bring you to reproach, and if you have a live conscience to cause unceasing self-condemnation.

If you feel restrained from immobilizing a healthy joint from any fears of ankylosis, let me comfort you with the assurance that in the treatment of ostitis of the hip immobilization has been maintained for a year at a time without ankylosis, and not in one case, but many. Further, that early ankylosis in the proper position as a sequel to hip disease should rather be sought than avoided. In this attempt there will be an entire avoidance of traumatism of motion and a more speedy arrest of the progress of the disease.

THE NERVOUS AND MENTAL PHENOMENA AND SEQUELÆ OF INFLUENZA.*

By CHARLES K. MILLS, M. D.,
PHILADELPHIA.

All practitioners have been struck by the prominence of nervous and mental phenomena in influenza, and much has been written, but mainly in a desultory way, about the symptoms of the disease which are referable to the nervous system, and its more or less persistent nervous and mental sequelæ. The part played by the nervous system in the etiology and history of the disease has been variously interpreted. One holds that it is a "nervous disease," without explanation; another describes it as pneumogastric neurosis; another as a neuropathy due to ptomaine poison. According to Blocq, cited by Church,[1] the primary infectious action takes place upon the nervous system during the disorder, while sequelæ are to be attributed to secondary infection from ptomaines. Cheston Morris,[2] of Philadelphia, advances the theory that the general symptoms of influenza may be traced to a derangement of function, or partial paralysis of the pneumogastric nerve, and that the affection is brought about by conditions of the atmosphere, which particularly tax the cardio-pulmonary apparatus which is regulated by this nerve, a view which, after all, relegates the disease to an atmospheric or infectious cause. Graves long ago referred the bronchial and pulmonary symptoms of grippe to lesions of the nervous power of the lungs, and Blakiston regarded it as a disorder of the nervous system, with concomitant derangement of the organs of digestion, circulation, etc. Levick,[3] who cites the last two authorities, holds that certain symptoms are produced when the poison is expended on the sensorium, and certain others when its influence is chiefly exerted on the respiratory centres.

The analogies or relationships between influenza and other diseases generally recognized as belonging to the nervous system, either primarily or because of the situation of their most notable lesions, have been strongly brought out by able writers, as by Levick, for example, who has even suggested that epidemic cerebro-spinal fever, or cerebro-spinal meningitis, may be simply a malignant form of influenza, a view to which he was led because of the resemblance in the symptoms of the two diseases, which differ in degree rather than in nature, and also because, for three centuries, the two have occurred coincidently or in close sequence.

Grasset and Rauzier,[1] in a monograph on the grippe of 1889–90, lay great stress on the enormous predominance of the nervous over the catarrhal elements in the epidemic, as evidenced in the high fever, great cephalalgia, the marked delirium, the widespread pain, and the excessive nervous irritability. They refer to cases communicated by M. Coustan, in which the entire symptomatology of the disease seems to have reduced itself to a horrible migraine. They review the literature, which shows that writers of various countries are unanimous in proclaiming the importance of the nervous element—referring to Austrian, Russian, Belgian, German, English, and Polish contributions.

According to Schmitz,[2] who read a paper on the subject before the Psychiatric Society, at Bonn, influenza is a disease of the nervous system with secondary involvement of the heart, lungs and digestive organs. In several hundred cases which he observed, the nervous sympsoms were always primary, followed in every case by secondary involvement of the other organs.

What seems to be needed is an analysis and practical grouping of the facts, almost too numerous to handle, which shows the important part played by the nervous system in the development, progress and results of the disease. How is the nervous system affected by influenza? What are its primary or direct effects on the nervous system, and what are some of the more persistent and permanent impairments, and how are these determined by the disease? What are its acute nervous and mental phenomena, and what are the most common sequences? What is the probable pathology of these states, and what treatment is best in view of the neurotic characteristics of the affection?

---

The briefest consideration of the subject brings forcibly to mind the fact that all diseases of infectious or toxic origin—epidemic, endemic, sporadic, or accidental—may strike any or all parts of the nervous system with a result which will be proportionate: first, to the virulence of the infecting agent; and, second, to the resistance of the individual, whether this is due to constitutional predisposition or to reductions the result of previous injury or disease. The microbes may differ, but a bond of union and close resemblance can be recognized between the effects on the nervous system of all contagious and infectious diseases, as variola, scarlatina, diphtheria, measles, whooping-cough, typhoid or typhus fever, leprosy, mumps, cholera, erysipelas, puerperal fever, influenza, or cerebro-spinal meningitis; of all of such constitutional and diathetic affections, as tuberculosis, gout, rheumatism and diabetes; and of all such toxic agents artificially introduced into the system, as alcohol, mercury, lead, arsenic, copper and poisonous gases. These diseases, these diatheses and these poisonous metals and gases produce, or may produce, nervous and mental phenomena of the same character, differing in degree in particular cases and for special reasons.

In all these affections at the time of acute onset, if the illness is of a serious character, such symptoms are present as great mental and nervous debility, irritability, restlessness, sleeplessness, or the opposite states of torpor, stupor, hebetude, or coma; delirium; vertigo or syncope; headache, browache, napeache, backache and limbache; pains of all degrees of severity referred to various nerve areas; hyperæsthesia of the skin, of muscle-masses, or confined to nerve-trunks or branches; spasms, local or general, and with or without unconsciousness; sometimes mental disturbance amounting to a true mania or melancholia. During the progress of such affections any one or several of these enumerated symptoms may be present. Supra-orbital pain, for example, may be the only prominent nervous symptom in a case of influenza; headache and backache in diphtheria; hyperæsthesia in mumps, diabetes, or gout; and mania in a case of puerperal infection. Any infectious or toxic disease may, in brief, produce the same symptom, syndrome, or train of phenomena; and—which is the main point—for the same reason, namely, because of the introduction into the system of an agent which directly and powerfully poisons nerve centres, and possibly also nervous conducting tissues.

Following all infectious, diathetic, or toxic diseases, moreover, or directly springing from them, common experience teaches that we may have great nervous or general weakness; forms of insanity of the depressive type; paresis and paralysis of every grade, from an affection of a single muscle to that of all the extremities, and even more; localized spasm or cramp; general convulsions; pains in nerves, muscles and joints, and losses or perversions of sensation.

These symptoms and conditions, which may occur at the onset, during, or after the subsidence of any infectious or toxic disease, are those which constitute the nervous features of the prevailing epidemic. I have introduced the subject in this way because it seems to me that it is this comprehensive grouping of generically similar phenomena which enables us to most readily grasp a subject even for practical purposes. We differentiate phenomena in our daily labor, which we can only understand by properly grouping them, and by referring them to a common or to related causes.

Any attempt to classify the nervous and mental phenomena of influenza must be attended with great difficulties. These are, in the first place, symptoms and conditions which, although manifested in non-nervous organs, are directly traceable to a nervous origin; secondly, affections which would be recognized by all as properly referred to the nervous system; and, thirdly, affections occurring in nervous tissues and organs, although, strictly speaking, not nervous diseases.

I will refer very briefly to the first of these classes, although of much importance. I will not, however, discuss the nervous origin of the fever of influenza, nor will I attempt to explain the catarrh, indigestion, etc., on some neurotic theory, as such a method might lead us anywhere, and for our present purposes would be unprofitable. I wish simply to emphasize the fact that some of the most prominent pulmonary, cardiac and vascular affections of influenza can best be explained on neural theories. Many personal observations have led me to the conclusion, not new, which has recently been well presented by Elliott,[1] of New Orleans, that the pneumonias of influenza are often due to vasomotor paralysis, that they are, in fact, forms of blood stasis or passive congestion from vasomotor paralysis, which, in its turn, is dependent upon the action of the infection upon the pneumogastric centres and the nervous system in general. A distinct difference can be made out between

[1] Elliott: *The Climatologist*, vol. I, No. 1, Aug., 1891.

the true pneumonic lung and this "grip-lung," as it has been termed by Elliott. Graves long ago attributed the œdema of the lungs which occurs in influenza to an affection of the vagus.

"The grip-lung," according to Elliott, "has a long and very varying condition of passive blood stasis unaccompanied by râles. If resolution occurs within three or four days, it is accompanied by large mucous râles, and no time is given for the slow appearance of bronchial breathing or bronchophony; but during the long continuance of the blood stasis, an exudation occurs, increasing slowly, which will give, in time, some bronchophony and bronchial breathing, but never so complete as in pneumonia. Resolution never occurs in these cases with the suddenness that characterizes it in acute pneumonia the condition passes off as gradually as it formed. The sharp, clear-cut and sudden phases of the pneumonic attack separate it clearly from the obscure, irregular and slow phases of the *grip-lung*."

Many disorders in various parts of the body are best explained on this theory of local vasomotor paralysis, although it is not necessary to attempt to force this explanation for all. Hæmorrhages, minute, or even of considerable size, occurring in diverse localities, as in the retina, membrana tympani, and internal auditory apparatus, or in the skin, or mucous or serous membranes anywhere, may be due to deficient vasomotor tonus. Brain, kidneys, liver, or pelvic organs may suffer from forms of passive hyperæmia, subacute or cronic, which are in fact due to forms of vasomotor palsy. Occasionally we meet with cases of vasomotor disorders of the extremities, such as flushed or pallid fingers.

Even tropic affections have occasionally been observed. Wilson,[1] for example, refers to gangrene of the lungs as one of the less common complications. Abscesses of the limbs have been recorded. Grasset records two observations of eschars occurring in young subjects in the absence of prolonged decubitus. The greater tendency in surgical cases to suppuration may have its best explanation in the depression of healthful vasomotor and trophic influence.

The peculiar forms of pulse, and the uncertain or perverted action of the heart, extending in some cases to cardiac palsy and death, are in a strict sense nervous phenomena due to paralysis, partial or complete, of the inhibitory apparatus of the heart.

Let me take up those symptoms and affections which would clearly be recognized as belonging to the nervous system.

I believe with Church, "that the infection of influenza has a marked action upon the nervous system which may give rise to immediate acute manifestations or to remote and persistent conditions; and that in the predisposed, grippe is competent to cause marked excitement or great depression of the motor, sensory, and mental nervous apparatus."

Great nervous and mental prostration, both as an acute manifestation and as a persisting sequel, has engaged the attention and required the treatment of all practitioners. The mental depression, often present as an initial symptom, has been in some cases, simply overpowering. Some of the patients are affected like individuals whose mental and motor centres have been poisoned to the limits of human endurance, while still permiting the retention of consciousness. In other cases even consciousness itself has been overwhelmed.

Not a few patients who suffered from attacks of influenza during the early period of the present epidemic are still victims of profound neurasthenia. I refer now to cases which are not distinctively of the melancholic type. These neurasthenics are unable to endure a fair amount of work; their nervous forces are soon routed; they are weak, worrisome, and unrecuperative. The cardiac weakness which has been left is undoubtedly in part the cause of this neurasthenia, and with reference to this Church says that "the persisting neurasthenic condition, which so usually follows influenza, is attributed by some to cardiac weakness of nervous origin, and this contention is not without weight, if it is observed that even after appetite, sleep, body-weight, and physical functions have been long restored, the slightest exertion immediately produces disproportionate fatigue accompanied almost invariably by either a retarded or more frequently accelerated pulse, and rarely by præcordial distress and even by angina pectoris."

Curtin and Watson,[1] whose experience in influenza has been enormous, say that although general nervous prostration often extended over long periods without any discoverable local cause, it was always worth while to examine the urine with care. "Sometimes a nephritis, sometimes a faulty digestion or hepatic inaction seem to underlie the general condition in latent form. These cases, by enforced rest and attention to local complications, gradually recovered. These

[1] Wilson: *American System of Practical Medicine*, vol. I., p. 870.

[1] Curtis and Watson: *The Climatologist.*

cases, and nervous cases generally, were very disappointing when sent to the seashore during convalescence."

Among organic nervous diseases which have developed during the influenza or have been left in its wake, are in the order of their frequency, so far as my personal observation has gone, neuritis, meningitis, myelitis, and cerebritis, or various combinations of these inflammatory affections, as, for example, concurrent neuritis and myelitis, meningo-myelitis, or meningo-encephalitis.

Probably no single affection of the nervous system has been so common during and after the grippe, and particularly as a sequel of the disorder, as neuritis. Almost every variety of neuritis, as regards location and diffusion, have been recorded, and have come under my personal notice. Multiple neuritis, while not common, has not been rare; and I have seen a concurrence of this affection with poliomyelitis in the same case. Isolated neuritis of almost every cranial nerve has been recorded, with such resulting conditions as optic atrophy, loss of smell and of taste, opthalmoplegias, both internal and external; oculomotor, facial, and bulbar or pseudo-bulbar palsies of various types, including true pnuemogastric paralysis. Several cases of specially located affections of the sympathetic ganglia or nerves have been recorded. Of the forms of local neuritis most common might be mentioned the supra-orbital, intercostal, sciatic, and plantar.

An interesting case of neuritis, with a myxœdemoid condition of the limbs, presented herself at the Philadelphia Polyclinic recently. She had a sharp attack of influenza five weeks ago, having been in good health up to that time, except five years since when she suffered for several weeks with inflammatory rheumatism. On recovering from the influenza, the attack not having been especially marked with nervous symptoms, she was extremely weak in the legs, and was scarcely able to drag herself around. In a few days her feet and legs began to swell and to be painful, and soon became of enormous size and exquisitely tender. She has gradually improved, but still has a condition of firm swelling, which does not pit on pressure, from her knees to her ankles, and she also still has great tenderness on squeezing the feet or ankles, or in handling the nerves or the muscles of the limbs. Shehas no cardiac affection.

The articular pain, and other so-called rheumatic manifestations so numerous during and after attacks of the grippe, are, after all, best explained on the theory of infectious neuritis or myositis.

These cases, with articular and other pains, and with swelling, recall the endemic or epidemic form of multiple neuritis, known as beri-beri, in which the chief phenomena are œdema and paralysis of the limbs, with marked pain, hyperæsthesia and paræsthesia, followed later by anæsthesia, lost knee-jerk, and depressed electrical reactions. Myositis certainly, and probably also periositis, occur as complications or sequences of the influenza, and usually in association with neuritis of some type.

Many of the reports speak of the frequent occurrence of various neuralgias. Doubtless a distinction is seldom made by observers and recorders between neuralgia and neuritis, which are or may be separate affections. Practically these cases should be regarded as neuralgic in which pain is referred to certain nerve lines or radiations, but in which pain on pressure, and the other phenomena of neuritis, such as anæsthesia, vasomotor and trophic disorders, and even paralysis, are absent. In my own experience the cases which could properly be diagnosticated as neuritis are by far the most common. The distinctively neuralgic pains are probably due to .toxæmically depressed or exhausted sensory nerve-roots or centres in the cord and bulb.

Of diseases of the spinal cord proper, occurring as complications or consequences of influenza, the reported cases are not numerous, but they are none the less important. A few cases of myelitis have been put on record by native and foreign observers—one that I recall in which all four extremities were paralyzed. As would be expected, in accordance with the analogies with other infectious and toxic diseases, anterior poliomyelitis is the most common type. I have had several cases of temporary paralysis of one or more limbs, which, owing to the absence of pain and of cerebral symptoms, were apparently spinal in their origin, and probably light forms of inflammation. Concurrent multiple neuritis and poliomyelitis has already been referred to as having been observed by me in one case, in which the neuritis, which was not severe, soon disappeared, but a limited paralysis, evidently spinal in character, was left behind.

Several observers having reported cases of bulbar paralysis, and one striking example of this disease, attributed to the grippe, has come under my own observation, although exactly how far the influenza was responsible it is difficult to say. This patient, a clergyman, had a severe attack of influenza in May, 1890, and during its progress continued to

work and ate but little. In a very short time he noticed he was losing power in his hands, which soon atrophied. In January, 1891, he began to have difficulties of speech, and, briefly stated, the case went on until November, 1891, when he was first seen by me, his symptoms were those of well-marked bulbar paralysis, with progressive muscular atrophy, chiefly involving the upper extremities.

In accordance with analogy, we would expect the occasional occurrence both of nuclear polioencephalitis, and even rarely Strumpell's cortical polioencephalitis. One or two of the few cases of probable polioencephalitis of the latter type have occurred in patients suddenly stricken with fever, loss of appetite, and other symptoms which may have been due to infection.

Priester[1] has reported the case of a man fifty-four years old, who was taken with influenza in February, and in the beginning of March was seized with extremely violent headache which resisted all medication, and later the patient became deeply somnolent, remaining in this condition for four weeks; he could be aroused, but was apathetic and soon slept again. Reflexes and temperature were normal; pulse from 40 to 60. The patient had no paralytic symptoms, and slowly improved. His affection, according to the reports of the case, closely resembled Gerber's disease — paralyzing vertigo — although the latter is a disease of the warm weather. Tumor could be excluded by the absence of all fœcal symptoms a year before the attack. The most probable cause he believed, was a pathological process, involving the central gray matter of the third ventricle, which would bring the disease into close relation with polioencephalitis of the nuclear type. Dr. G. J. Kaumheimer, who translated this report for the *Review of Insanity and Nervous Disease*, December, 1891, observed an exactly parallel case which originated in April, and lasted into July before recovery took place.

That meningitis, either cerebral, spinal, or cerebro-spinal, occurs during the decline of the influenza cannot be doubted in the light of the evidence which has been presented by various observers, and particularly during the epidemic of the last three years. It is, however, a comparatively rare concomitant or complication. Some of the facts adduced as proofs of the existence of meningitis, and some of the cases reported as examples of the disease are clearly instances of improper interpretation. The intense cephalalgia and rhachialgia; the atrocious pains variously localized in the face, trunk, limb-nerves, muscles or joints; the vigilant delirium, with hallucinations and delusions, sometimes assuming great gravity; the intense vertigo, with or without nausea and vomiting—these and other well-known nervous manifestations which are so prominent in many cases at the initiation of the disease, are not necessarily evidences of meningitis, or even of meningeal hyperæmia. Rather they are due to an overwhelming toxæmia of the nerve centres and of the brain. Severe and terrible in character at first, they frequently pass away almost as rapidly as they came, which would not be the case if they were the evidences of a true meningitis. The enormous prostration which is left behind shows that the centres of nervous energy have been subjected to a depressing agency of great virulence, not that merely enveloping membranes composed mainly of fibrous tissue and blood-vessels have been congested or inflamed. No reason could be given why such congestion or inflammation should leave such results.

The reports of cases terminating fatally because of meningitis, and even the reports, personal or official, of the frequent occurrence of this affection must be received cautiously, and sometimes incredulously. They are only to be relied on when confirmed by autopsies, or when from observers who are accustomed to closely differentiate the meaning of nervous symptoms, and particularly of pain.

It may also be worth while at this point to refer to the somewhat frequent diagnosis of chronic meningitis as one of the sequelæ of the disease. This diagnosis is usually made because of the presence of more or less persistent pain in or on the head. Experience has led me to believe that this pain is usually neuritic rather than meningeal. Even deep-seated intra-cranial pain does not necessarily indicate meningitis. They may be due to neuritis, just as certainly as a pain in the hand or foot. The fifth nerve has an immense distribution within as well as outside the cranium, largely to the dura mater, but also to other tissues and parts. It is a pathological possibility to have dural neuritis without a pachymeningitis, and this is the true explanation of some pains, both acute and chronic, which are present in other diseases, as well as in influenza.

The form of meningitis most likely to be present in influenza is inflammation of the

[1] Priester; *Wein med. Woch.*,No. 27, 1159. In *American Review of Insanity and Nervous Disease*, December, 1891.

pia-arachnoid, or soft membranes, now often designated lepto-meningitis. From observations, corroborated by autopsies, I know that this affection may exist without pain; while pain of varying degree of severity, and usually intense, is practically invariable in pachymeningitis. Lepto-meningitis, however, is not usually without pain and hyperæsthesia as symptoms, but it may be absent, and its presence or absence will depend upon the location, extent, grade, and complications of the meningitis.

While believing that these criticisms upon the sometimes hasty, and the too frequent diagnosis of meningitis in influenza, and, indeed, in many other infectious and febrile diseases, are just and can be sustained, it remains true that a genuine meningitis, sometimes of malignant type, may appear during the progress, or closely following, influenza. Some very competent observers have reported cases of this character, and in a very few instances the diagnosis has been confirmed by autopsies. The diagnosis should be made to hinge upon the signs and symptoms which would be satisfying as to the occurrence of meningitis from any cause; not alone on the presence of such phenomena as headache, vertigo, and vomiting, but on such more convincing manifestations as optic neuritis, and localized spasms or palsies, either cortical or of cranial nerves.

The fact that meningitis, and even the cerebro-spinal form, does occasionally occur in influenza, is by no means proof that this disease and epidemic cerebro-spinal fever are identical. It simply emphasizes the point with which I started, namely, that every infectious or poisonous agent introduced into the economy may produce the same or similar pathological results in the nervous system. Largely according to the vulnerability, special or general, of certain tissues and organs, will be the preponderance of this or that form of so-called disease—for instance of neuritis, myelitis, meningitis, cerebritis, or of combinations of these affections. All infectious and toxic diseases give neuritis as the most common acute or chronic inflammatory manifestation, although myelitis, cerebritis, and meningitis may occur. Even in cerebro-spinal fever, as I was perhaps the first to point out, multiple neuritis is a common complication; but the infection being virulent and overwhelming, we may not only have mengigitis, but even meningo-encephalitis, or meningo-myelitis, with all their malignant phenomena and permanently disastrious results.

Vertigo is another symptom, like pain, often improperly referred to meningeal or cerebral inflammation. It is sometimes due to such disease, but occurring in influenza it may arise from other causes, as, for instance, from extravasations into the labyrinth or other portions of the auditory apparatus.

Müller[1] reports the case of a man, 50 years old, who, after influenza, presented great physical exhaustion. In a few weeks his mind seemed affected, and he became somnolent, so that he could be roused only with difficulty, and would then fall asleep again. In this respect the case was much like the one reported by Priester. Pain upon pressure was present over the vertebræ, the neck was rigid, the pulse was small and irregular, the skin reflexes were diminished, and the tendon reflexes were absent. In two weeks he began to improve. The author believed the case was one of spinal cerebro-spinal meningitis, similar to that seen after infectious diseases.

Without entering into discussion of their pathology or their peculiarities, I will briefly mention a few other forms of nervous disorder, occurring during or as apparent sequelæ of the influenza, examples of which have come under my personal observation. Convulsions have been reported by various observers, and in a few instances the convulsive habit has been established, and the patients have remained up to the time of report as cases of epilepsy. I have seen two such cases. Hystero-epilepsy and other grave hysterical phenomena have been initiated, or have recurred in cases in which the symptoms had long been dormant. Of local spasmodic affections I have seen no records, but one case of persistent clonic torticollis, with some pain and tenderness in the spinal accessory distribution, has been in attendance at the Philadelphia clinic. Two cases of facial paralysis, occurring immediately upon the heels of influenza, have come under observation.

Many affections not of, but occurring in, the nervous system have been reported as complications or sequences of the influenza. These include such affections as apoplexy, due either to hæmorrhage, thrombosis, or embolism. One of my Polyclinic patients, a man thirty-seven years old, was attacked with influenza in January, 1890. He was not confined to bed, but suffered severely from headache, cough and persistent general weakness, and in February he was suddenly paralyzed in the right half of his body, and completely aphasic. Well-marked cardiac murmurs were present, and the grippe in this and similar cases is probably causative by lightening up old endo-

[1] Müller: *Berlin klin. Woch.*, No. 37, 1890—cited in *American Journal of Insanity and Nervous Diseases*, December, 1891.

cardial trouble, or through the blood dyscrasia and general prostration which it leaves.

Various observers have reported cases of monoplegia and hemiplegia, without indicating the pathological character.

Recently, in consultation, I saw a typical hæmorrhagic apoplexy occurring in a case of influenza in a woman about sixty years old, who had previously been in fair health, and was not known to have had any disease of the kidneys or heart, although her vessels were somewhat atheromatous. Dr. S. S. Prentiss,[1] of Washington, has reported three cases of cerebral apoplexy occurring during the progress of the influenza: one was a man of fifty-seven years of age; another in a man of eighty-seven; a third in a woman of sixty-seven. One of these was probably hæmorrhagic, the other two, from the histories, were probably from thrombosis. In cases of this character the infection of the disease acts to bring about an apoplexy both by the changes which it produces in the blood, by its effects upon cardiac actions, and by the general debility induced. Such apoplexies might occur from other depressing causes; they are to be regarded not as phenomena, but rather as accidents of the epidemic.

Uræmic convulsions in patients suffering from chronic Bright's disease have been precipitated by the influenza, and it has seemed to me to have been active in lighting up lurking syphilitic diseases.

In one case of paretic dementia of somewhat irregular type, seen in consultation, the initial symptoms of the disorder were observed soon after recovery from a severe attack of grippe, the wife and friends of the patient in fact attributing the mental disorder to this attack. The probabilities are that syphilis was present, but latent, prior to the epidemic.

Purulent meningitis and brain abscesses have been somewhat frequently noted in connection with the numerous instances of purulent otitis media.

The relations of influenza to insanity have not received much attention from writers. Mairet,[2] of Montpellier, has recently published a lecture on the subject delivered at his clinic for mental and nervous diseases. Rush, who is referred to by Mairet, speaking of the epidemic which lasted from 1789 to 1791, and particularly of the year 1790, mentions that several persons were stricken with symptoms of insanity, and that one attempted suicide; he also speaks of several having had hallucinations of sight. Bonnet, reporting on the epidemic of 1837, cites one case which was stricken with a furious mania as the result of the grippe; and Petrequin, referring also to the same epidemic, records several patients tormented by melancholy ideas, and states that four or five suicides were accomplished or attempted at the hospitals in Paris.

The following conclusions compress into small compass so much that is valuable, with reference to the relation between influenza and the psychoses, that I cannot do better than quote them. They are reported as the conclusions arrived at by Dr. Leledy, and were presented to the Medical Society of London by Dr. Savage:[1] 1. Influenza, like other febrile affections, may establish a psychopathy. 2. Insanity may develop at various periods of the attack. 3. Influenza may induce any form of insanity. 4. No specific symptoms are manifested. 5. The roll of influenza in the causation of insanity is a variable one. 6. Influenza may be a predisposing or exciting cause. 7. In all cases there is some acquired or inherited predisposition. 8. The insanity is the result of altered brain nutrition, possibly toxic. 9. The onset of the insanity is often sudden, and bears no relation to the severity of the attack of influenza. 10. The curability depends on general rather than on special conditions. 11. The insane are less disposed to influenza than are the sane. 12. In rare instances, influenza has cured psychoses. 13. The insane may have mental remission during the influenza. 14. There is no special indication in treatment. 15. Influenza may lead to crimes and to medico-legal issues.

I can indorse from experience almost every one of these conclusion. With reference to the statement that no specific symptoms are manifested, it should be said that while this in a general sense is true, the most frequent type is a form of melancholia.

The cases of active insanity have been observed at the onset of influenza and during its height, but more particularly during its period of decline and convalescence. The published cases had been recorded chiefly as instances of acute mania or melancholia. The commonest type of grippe mental disorder, as I have just stated, is a form of melancholia or lypemania; but as this not infrequently assumes the form of melancholia agitata, it is often regarded as mania by practitioners not accustomed to differentiate the varieties of insanity. These patients are intensely depressed and emotional; they are filled with

[2] Mairet: *Grippe et Alienation Mentale.* Montpelier and Paris, 1890.

[1] Savage: *Lancet,* No. 3558, and *Medical News,* January 16, 1892.

apprehensions of disgrace and ruin; they believe that they will never recover their former health; they are suspicious and delusional with reference to those who surround them; they are frequently unwilling to eat, or to rest, or to take medicine, and in some cases they have definite delusions of terrible character, for the most part hypochondriacal or religious. They are frequently plagued with the thought of suicide, and some times make successful or unsuccessful suicidal attempts. They have been deprived, by the ravages of the disease, of mental and moral stamina. In the majority of these cases, but not in all, some hereditary or acquired predisposition is present. While, however, the grippe usually gives us mental disorder of special type—a form of delusional melancholia—under special conditions it may be the starting point or exciting cause of any variety of mental disorder, as mania, paranoia, paretic dementia, hebephrenia, etc., but I can no more than glance at this phase of the subject.

The investigations of Church show that in each year in Cook County, Illinois, the epidemic of influenza has been attended by an increase in the number of proceedings for the commitment of the insane, which he believes cannot be explained by increase or movement of the population of the county.

Of the influenza occurring in hospitals for the insane, I have had no opportunity for observation, except in connection with the insane department of the Philadelphia Hospital. A great disproportion has been observed between the number of cases occurring among the women and the men. One hundred cases are recorded as having occurred among four hundred and sixty female patients; and only three in a larger number of men. The disease did not prove particularly disastrous among these patients, only three deaths having occurred from pulmonary complications. The cases were, as a rule, not of severe type; less severe than in an equal number of sane patients.

K. Helweg[1] has recorded the results and action of influenza in the Asylum at Aarhus, Denmark, and Pritchard has translated and summarized this paper for the *Review of Insanity and Nervous Disease*, for December, 1891. The account is of such interest that I will give it in detail: "The disease appeared in the asylum January 4, a few weeks after it had first been observed in the neighborhood. Out of 520 insane, 41 were so severely attacked that they were confined to their beds. The disease seemed decidedly contagious. It spread with difficulty on account of the wards being divided one from another. Eight of the twenty-five wards were spared altogether. When a ward would be invaded, the disease would rapidly run its course, to proceed to another. The transmission of the contagion could be distinctly seen in the sick wards where those stricken down in the other wards would bring the disease with them and transmit it to patients there. Seven patients had pneumonia. A relatively large percentage (six) died, of which four were from pneumonia. Among these was a man with such a severe cerebral disease that he must be excluded (the post-mortem results in the remaining five, which were women, were all more or less similar). The most essential results were extreme hyperæmia of the cranial bones and membranes, where the dura and the brain mass itself twice presented fresh and strongly vascular pseudo-membranes with small hæmorrhages as well. The veins and arteries of the thinner cerebral membranes were filled to bursting with blood; the large basal arteries were so filled with coagula that they stood out like cords. or those of an injected specimen. The brain substance itself was very hyperæmic, and its consistence increased. The average weight of these brains was about the ordinary of those of Aarhus. The writer also gives the history of the man mentioned, and those of the three other cases where influenza could not be diagnosticated during life, including the post-mortem findings of a case of influenza in a (sane) nurse who died of pneumonia. Here also was great hyperæmia of the brain and its membranes, yet not so pronounced as in the insane cases. The writer has seen influenza accompanied by severe psychic symptoms. In a few cases, the condition resembled acute delirium, which, however, is transient, and seems easily controlled by antifebrin. On the contrary, in two hopeless cases of insanity the disease had such a favorable and curative action that they may be regarded as cured. In both cases there was pneumonia."

The epidemic influenza has impaired the *morale* of the community. Lack of spirit in work, and an apprehensiveness with reference to health, business and all matters of personal interest are abnormally prevalent. The hysterical have become more hysteric; the neurasthenical more neurasthenic. Hypochondria has displaced hopefulness in individuals commonly possessed of courage and fortitude. In brief, certain neuropathic and psychopathic features have been impressed upon the community. We cannot afford

[1] Helweg: *Hosp. Didende*, R. 3, Bd. viii., S. 729.

even to dismiss entirely from consideration the bearings of the epidemic upon the increase not only of suicides, but of other grave crimes.

Many interesting questions in connection with treatment might be discussed; but as the subject of treatment has been assigned in this discussion to Dr. Hare, I will only speak of one point.

The use in influenza of hynotics, narcotics, sedatives and motor depressants is a question of particular interest in connection with the study of the nervous and mental phenomena of the disorder. The views of practitioners and writers are here decidedly at variance. Serious mental and nervous complications or actual insanities occurring during influenza have been attributed to the too free use of such chemically powerful remedies, as phenacetin, antipyrine, antifebrin, choral, bromides, sulfonal and paraldehyde; and our older narcotics such as opium, hyoscyamus, conium and cannabis Indica, have also come in for a share of blame. Persisting conditions of nervous prostration, and chronic respiratory and cardiac neuroses, have also been charged to drugs. Undoubtedly such criticisms have some foundation, but it remains true that each of the remedies named has proved itself of some value in the treatment of influenza, and particularly of its nervous types. The enormous consumption of a drug like antipyrine is a practical argument both for and against its use. What Grasset has said of this remedy might with almost equal truth be said of almost any of the rest. "This agent," he says, "vaunted by some as a panacea against all manifestations of the disease, is considered by others a remedy absurd and irrational in all cases." The truth would seem to reside between these two extreme opinions."

NEW STUDIES OF SACCHARIN.

C. Kornouth (*Ber. d. Deutch. Chem. Gesellschaft*) reports as the result of extended experiments that saccharin notably hinders the fermentation of beer yeast, and virtually stops it so soon as the amount added reaches 5 per cent. Other micro-organism, however, appear to be less easily affected by the agent, and some are entirely indifferent to it. Administered, even in enormous doses, for a long time to dogs, ducks, hogs, etc., it had no apparent affect either upon the weight of the animals or upon their appetite for other foods. None of the animals showed any aversion to saccharin or to articles with which it was mixed, and which they ordinarily ate.

IDEAS OF LUKJANOW ON THE PATHOLOGY OF THE CELL.*

By AUTHUR MacDONALD.
GEORGETOWN MEDICAL SCHOOL, WASHINGTON, D. C.

Whether there is a fundamental difference between the pathological and abnormal is unknown. A sixth finger is sometimes given as an illustration of the abnormal only; but this may be due to a pathological process in utero. On the other hand, the basis of the pathological seems to rest in the last analysis upon the abnormal; or abnormal increase of the physiological. It may not be uninteresting therefore to follow Lukjanow in some of his ideas on the pathology of the cell.

A general pathology of the cell treats of the forms of functional disturbances in the life of the cell. Here we should distinguish sharply from pathological histology, the main object of which is to establish morphological laws. Cellular pathology has also to show how far functional disturbances may be derived from morphological changes. The constructing of the pathology of the cell is at first beset with numerous difficulties. Omitting morphological questions and passing over to physico-chemical characteristics of the normal cell, we must admit that concerning these latter we know very little. Yet behind the morphological structure stands the physico-chemical.

But an investigation of the pathology of a cell presupposes that the normal life of the cell is reduced to a series of more or less exactly determined functions. But such is not the case.

The ideas concerning the functions of growth, nutrition, multiplication, motion and feeling are very far from clear. There is rather a maze of contradictions. One of the greatest difficulties is that the relation between the morphology and function of a cell is for the most part a complete enigma. The most fundamental of all questions in cellular biology, is whether the cell is an elementary organism. The investigations of the present throw serious doubt upon this, and show that the cell is rather a complex organism, just as the bodies of the higher animals and plants are composed of cells. According to Altmann[1] the active "*granula*" are, like the cells themselves, living elements, capable of multiplication; the granule has

*Lukjanow, S. M.—Grundzuge einer allgemeinen Pathologieder Zelle. Leipzig, 1891.

[1]Die Structive des zellkerness Archiv. von Du Bois Reymond, 1889.

the same relation to the cell as the cell does to the whole organism. In certain cells according to Steinhaus,[1] the "*neucléole-noyau*" can be a parasite. The solution of the question as to what forces bring the moving parts in the direction of this or that nourishment seems to lie in chemism.

Cells have sensibility, the elementary form of psychical activity.

It is said that no lifeless object can be diseased; but from the mechanical stand-point no definite line can be drawn between lifeless and living nature; an irregularly formed crystal is like to an irregular growing diseased cell.

According to Virchow, the substratum upon which pathological manifestations play, is a repetition or reproduction of the normal morphological substratum; this shows that the fundamental principles of structure in the elements of newly formed pathological tissue are the same as in normal tissue. The pathological character of the morphological substrata consists in this, that they arise in an unfit way; at the wrong place or time; or they may diverge from the type of the body depending on an abnormal increase of the number of the tissue-elements ("*hyperplasia*"). Thus every heterology is either heterotopy (*aberratio loci*), or a heterochrony, (*aberratio temporis*), or merely a quantitative deviation, a heterometry, which rests upon an abnormal increase in volume of the single morphological elements—a *hypertrophia*. A neoplasm can be heterological as to tissue, place or mass. Heterology signifies a difference in species in the type of the development of the new as opposed to the old, or as one is accustomed to say in degeneration, deviation from the typical form (Virchow).[2]

The heteroplasia, in the narrow sense of the word, is a deviation of the type of development of the tissue, and not merely in the outer conditions of its genesis. Cohnheim has sought to reduce all to anomalies of embryonic development, which lead to a remnant of embryonic germs in mature tissue; but he succeeded only in gaining intimations. In short, there is no reason to assume in the cells an independent function with the task of a transforming character; the cells in pathological relations *preserve their specific character just as they do under normal relations.*

If a parallel incision to the long axis is made through a "stentor," yet not the whole length, the parts do not fall to pieces; each one forms the failing part anew, and in this way we obtain twin forms, whose end (behind or before) is doubled, while the other end remains single[1]. From this we see that teratological forms, at least in certain cases, are nothing else than results of regenerative processes, which followed from outward "*insulte.*"

The whole doctrine of the immortality of the monoplastidiæ is still a hypothesis, which needs further investigation; for the cell is very probably a complex whole.

Under pathological conditions, nothing new arises in the cells, either morphologically, physico-chemically or functionally. The pathology of the cell is contained *in potentia* in its physiology. The general biology of the cell will be complete when its normal and pathological physiology has been united into a harmonious whole. We call a certain phenomenon in the life of the cell diseased, if it proceeds with a tangible injury to the cell; that is, if the cell deviates from its normal way, and so much that the return to its path is either questionable or plainly impossible. In normal conditions cells in the organism die; but this is to be distinguished from their premature dying. In general, it can be said that the group of physiological phenomena is characterized by a general tendency to the maintenance of life; while the group of pathological phenomena shows a tendency to destroy life.

As before indicated, investigations show more and more that the cell is no simple whole but a compound one; the single parts which constitute its morphological structure are, to a certain degree, independent; accordingly the pathological disturbances in the life of the cell can be considered not only in relation to the cell as a whole, but also in relation to single elements in its structure.

Between the body and the nucleus of the cell, there exists a very close relation, whereby in the action between the two, the most importance is attached to the cell-body. The essence of this relation in its universal form can be reduced to the nourishing of the cell. It is very probable that the indirect transmission of nutritive matter from the nucleus into the body of the cell, is in the life of the cell as a whole of greater importance than the delivery of the products of life of the body to the nucleus.

A PROTEST AGAINST CARELESSNESS IN THE EXAMINATION AND TREATMENT OF FEMALE PATIENTS.*

By M. B. WARD, M. D.,
PROFESSOR OF GYNÆCOLOGY, KANSAS MEDICAL COLLEGE, TOPEKA, KANSAS.

The members of our profession are, as a rule, desirous of obtaining knowledge at any reasonable sacrifice of time and money. We, therefore, leave our homes, our practice, and often very sick patients, and wend our way to Medical Societies and Medical Centres and go out of our way to gather a little here and a little there, with the one purpose in view, viz.: The better to fit ourselves for the great responsibilities of the general practitioner or the specialist. The physicians' sacrifice of time, money and life's comforts to serve their *clientele* is not excelled by any other calling or profession. Our most intimate friends, and even our near relatives, have but a faint conception of the everyday toil and midnight study of the earnest, honest and busy physician and surgeon.

Most of the essays read at Medical Societies and lectures delivered in Medical Colleges are prepared when other people are in bed and enjoying their rest, while the physician is toiling and studying how best to relieve suffering, prevent disease and to save life. Whatever of profit there may be in carrying out this great scheme of life preserving, it cannot for one moment be compared with the comfort of knowing that what we have done for our patients was the wisest thing that could have been done, and that no one could have done better. This is a standard of perfection which we should all strive to attain. In spite of our endeavors, however, to do the right thing at the proper time, we often come short of the mark. The field is too large and the complications too numerous, and thus the necessity of dividing our work, that some may go East, and some West, some North, and some South, in search of truth and experience, and then come together at these various Medical Society meetings and unload at the feet of all the facts we each have garnered, keeping nothing back; and, after reviewing our work and comparing notes with each other, we disband to go out again to do better work, more good and to receive our reward. We do not always get credit for the good we have done—but often we are praised for bad work performed. I believe in the general rounding up the world is fair and is usually correct. We may deceive our friends sometimes, but not always.

It has been both my misfortune and pleasure to have had only recently two cases which will clearly illustrate the danger referred to. I say misfortune, because it is unfortunate to be called to examine and treat grave cases which have baffled other, and perhaps better, surgeons; and it is a pleasure, on the other hand, to be conscious that our diagnosis and treatment were correct and satisfactory. I have selected these two cases to report at this time for the following reasons: First, they gave unusually obscure histories of pelvic disease, which fact alone will, I am certain, convince you that these conditions are more common than formerly supposed; second, they both had been East to consult prominent men, and both returned home not benefited; third, they are physicians' wives, and the history of their suffering and relief comes home to us with more than ordinary emphasis; fourth, I have been urged by their husbands, both prominent men in our profession, to report these cases.

Mrs. Dr. S., aged 24, gave the following history: Born and raised in Kentucky, surrounded by all the luxuries of Southern life, she passed her girlhood without any serious illness. Her menstruation was often painful, but not serious enough to attract any special attention. She married at nineteen; gave birth at twenty. She was in fair health and strength until about two years ago, when she began complaining of her left side, much suffering during menstruation, insomnia, extreme nervousness, great tenderness in both ovarian regions, but worse on the left side. This state of things increased until she was taken to Louisville, Ky., and consulted a prominent professor in that city. She was assured that nothing was wrong with the uterine adnexa, but that there was a slight endometritis. She returned to her home in S——., in this state, and settled down to her fate, i. e., to suffer the balance of her life. She consulted me about two month ago, and upon examination I found quite a mass on the left side, an adherent uterus, great tenderness on both sides, with a history of two attacks of pelvic peritonitis.

I diagnosed her trouble double salpingitis and ovaritis with adhesions everywhere, and without hesitation recommended an early operation for removal of the left appendages, and perhaps, also of the right. As soon as the doctor could arrange his affairs, he came

* Read before the Golden Belt Medical Society, in Salina, January 7, 1892.

with his wife to Topeka, and I removed these tumors.

Mrs. S—— convalesced in twenty-four hours, was up and as well as ever in two weeks; and returned home, over two hundred miles, in three weeks after the operation. The signs of suffering so plainly marked in her face have entirely disappeared, and she is now a rosy cheeked, bright faced young woman.

The gratitude of the doctor and his estimable wife is unbounded.

Mrs. Dr. M——., age 39, gave the following history: As a girl she was surrounded by all the comforts of life, yet she had always been quite a sufferer at her menstrual periods. Married at the age of twenty-six; had not borne children, For a number of years had been constantly a semi-invalid.

Her suffering was confined principally to her back and sides. So nervous was she that the least excitement would make her quite ill. She had much trouble from irritation of the bowels, particularly the rectum. When unusually nervous there would be a constant tenesmus which often amounted to frequent mucus discharges that annoyed her extremely. This condition led her to conclude her trouble to be entirely rectal.

The doctor at last became desperate regarding his wife's condition, and took her to Pittsburg, Pa., to consult an eminent physician of that city. He examined her, and pronounced her trouble entirely rectal, and treated her by dilating the rectum. This put her in bed for some time, and yet, it seemed to help her subsequently. At least she was for a time somewhat improved. She was assured by the Pittsburg physician that there were no signs of diseased appendages. Since her return home she has been treated for rectal trouble by a second dilatation, which again caused her to be quite ill for some time.

Mrs. M—'s, condition gradually became more desperate, until she had given up all hope of recovery. I was called in to see her about November 15, 1891, and after reviewing her history as given by herself and doctor, I made an examination of the rectum, then the uterus and appendages through the vagina, and also a second time by the rectum.

I found a prolapsed and adherent right ovary. The tenderness of these organs made the examination quite painful. I had no trouble to convince them that the rectum was not, at that time, diseased, and so far as I could judge, never had been. The rectal irritation was due entirely to the prolapsed and adherent ovary which had drawn the uterus down in a retroflexed position and was holding it there. This position of these organs caused a constant dragging down on the rectum, and naturally constant suffering.

I recommended the removal of the left side without delay, and advised them that in all probabilities both sides were entirely destroyed by adhesions. The operation was done four weeks ago to-day, (Jan 7, '92), and the patient went home, or left the hospital in less than four weeks from day of operation.

The operation was one of the most difficult I have ever had. The left tube and ovary were greatly enlarged and universally adherent to each other. They were adherent to the intestines so that it was very difficult to separate them, it requiring all my strength to remove them. The right side was quite as firmly adherent as the left, and the pathological condition about the same. The fimbriated extremities of both tubes, you will see, were occluded by large sacs of cystic fluid. The operation confirmed my diagnosis.

The condition found, was, in short, prolapsed adherent and enlarged ovaries; double hydrosalpinx, with large cysts in the fimbriated extremities of the tubes, entirely shutting off communication between ovaries and uterus; retroflexed and adherent uterus; and intestinal complications.

Mrs. M—— has had no trouble with her bowels since the operation. She made an uneventful recovery, with the exception of a severe attack of *la grippe*. She was up and around the house in three weeks from the time of the operation. She is as happy as any one can be, unless it be her husband. In the place of care-worn features, she looks as bright and fresh as a young girl. This is not an over-drawn picture.

I could refer to a number of cases of this character, which have come to my knowledge recently, but these are quite sufficient to illustrate my point. The country is full of women who are suffering from these conditions, as only women can suffer. Let us, therefore, be more thoughtful in our diagnosis and treatment.

SULPHURATED LANOLIN.

Seibel of Germany heats together crude lanolin with 20 per cent. of sulphur to a temperature of 120° C., until the greater portion of the sulphur becomes dissolved. The decanted dissolved portion is heated to 230° C., or until hydrogen sulphide vapors begin to evolve. The product is of a dark brown color, and will be used in the manufacture of sulphur soap principally. Seibel obtained a patent.

DOES ETHER ASSIST DIGESTION?

The effect of ether on the digestive processes in healthy subjects has been recently investigated by Dr. Gurieff, who gave thirty drops of sulphuric ether to six healthy persons during dinner, which consisted of about half a pint of soup, four ounces of meat, and six ounces of bread. It was found that the ether had the effect of stimulating the action of the gastric glands, increasing the free hydrochloric acid in the gastric juice, and causing the peristaltic movements of the stomach, together with its power of absorption to increase, thus, on the whole, exercising a favorable effect upon the gastric digestion. The same result was obtained when the ether was administered by means of hypodermic injections. It would appear, therefore, that the effects must be ascribed to a general, rather than to any merely local, action on the mucous membrane of the stomach. Dr. Gurieff is disposed to think that there is a stimulation of the cephalic centres. This view is partly based on the observations of other Russian observers—Bekhtereff and Miloslevski, and Pavloff and Shumova-Simanovskaya—on the dependence of the gastric functions upon the central nervous system.—*Lancet.*

THE CONSTITUTION OF THE SWEAT.

From a study of the constitution of the secretion of the sudoriferous glands, Gaube (*Comptes Rend. des. Séances de la Soc. de Biol.*, November 6, 1891) has found that the sweat is of acid reaction in man, but alkaline in the horse, the cow, the dog, the cat and the pig. Both in animals and in man the secretion contains albumen. The total amount of nitrogen in the sweat is greater than that represented by the contained urea; the excess is largely due to the presence of albumen and albuminoids. In man and in animals the sweat contains diastasic ferments, which are called hidrozymases. In man there are three—an amylase, a pepsin, and an emulsin. In the horse there are two, an amylase and an emulsin. The sweat of man contains little amylase, less pepsin, and still less emulsin; that of the horse and of several other animals contains less hidrozymases than does the sweat of man.

SELECTED FORMULÆ.

HIVES.

Dr. J. J. Liggett commends the following in the *Med. World:*

℞
Potassii iodidi.....3 v.
Vini colchici sem.....3 j.
Tr. cimicifuga rac.....3 ij.
Tr. stramon.....3 ss.
Tr. opii. camph.....3 iss.
M. Sig. From gtt. xv to 3 j, three times a day.

BRANDY WITH EGG.

To administer brandy to infants, Elroy recommends the following:

℞
Brandy.....f 3 i.
Cherry-laurel water.....gtt. v.
Yolk of egg.....No. ij.
Powdered sugar.....3 vi.
M. Sig. To be given in the course of a day, a small spoonful at a time.

—*Rev. de Clin. et de Thér.*

SEMINAL EMISSIONS.

℞
Potassi bromide.....ounce 1.
Tr. ferri chlor..... " 1.
Aqua pur.....ounces 3.
M. Sig. One or two teaspoonfuls in water one hour after meals and at bedtime.

—*Canada Lancet.*

SCIATICA.

Concerning this disease, Dr. Eliot, New Haven, Conn., makes the following suggestions (*New York Medical Journal*):

1. A large proportion of cases of sciatica are neuritis, and not simply neuralgia.

2. Temporary relief of suffering should be secured by hypodermic injections of morphine and atropine, or of theine.

3. Among curative agents, salicylate of sodium and iodide of potassium are especially valuable—the former in acute, the latter in chronic cases.

4. Considerable benefit may often be derived from the administration of the more purely neurotic drugs—aconite, belladonna and gelsemium, as:

℞
Ext Belladon., fl.....drachm ½.
Ext Aconiti., fl.....drachms 1½
Ext. Gelsem., fl.....ad " 6.
M. Sig. Give six, seven or eight drops every four hours.

5. Cantharidal blisters are of great service in promoting the cure of the disease, when used in conjunction with appropriate internal treatment.

HAIR WASH IN SEBORRHŒA CAPITIS

(particularly in women with long hair).

℞
Ether spirits.....parts 1000.
Benzoin tincture..... " 100.
Vanilin.....part 1.
Heliotropin.....parts 3.
Geranium oil..... " 2.
Use externally. Pour a tablespoonful on the head once a day, after washing (or without previously washing), and rub-in with a fine cloth. (Inflammable!)

—Leibrich, *Ther. Monat.*

PAINLESS DILATATION OF THE OS UTERI.

Dr. R. Lefour (*La Semaine Médicale*, No. 50, 1891) soaks his laminaria tents eight days in the following solution before using them to dilate the os uteri:

℞ Ether.....grammes 85.
Iodoform.....“ 10.
Cocain, pur.....“ 5.

He prefers the pure alkaloid, cocaine, to its salt, the hydrochlorate, as the anæsthetic action of the cocaine salts is less than that of the pure alkaloid.

IRRITABLE HEART.

The *Indiana Medical Journal* gives the following:

℞ Tinct. pulsatillæ.....♏ xx.
Tinct. verat. viride.....♏ xl.
Ext. chimaphila, fl.....℥ j.
Syr. limonis.....℥ ij.
M. Sig. Teaspoonful before meals.

ROUND WORMS IN CHILDREN.

The following (*Centralblatt für d. ges. Therapie*, No. 8, 1891) is praised as a useful rectal injection in cases of round worms in children:

℞ Naphthalini.....grammes 1–1 50.
Ol. olivæ.....“ 40–60.

STOMATITIS IN CHILDREN.

Where the trouble is extensive and painful, the *Province Médicale* recommends the following treatment:

1. The gums should be brushed with—

℞ Cocaine hydrochlor.....gr. iss.
Sodii chloridi.....gr. xv.
Glycerin,
Aquæ.....āā 5 ijss.
M. Use a camel's-hair brush.

2. A spray of a solution of boracic acid should be frequently used.
3. Bromide of potash internally.

ANTISEPTIC ADHESIVE OINTMENT.

The following is an antiseptic adhesive ointment used at the Hôpital St. André:

℞ Zinci oxidi.....gr. ivss.
Zinci chloridi.....gr. xxiiss.
Gelatin.....5 v.
Aquæ.....℥ viiss.
M.

The dressing protects the surface of wounds and dispenses with the use of bandages after operations. It is especially of service for the dressing of wounds on the face.—*Gaz. Heb. des Sci., August 16, 1891.*

ORCHITIS.

℞ Ammon. muriate.....drachms 2.
Sprts vini, rect.....ounces 2.
Aquæ.....“ 2.
M. Sig. Use as a lotion

—*St. Louis Courier of Medicine.*

ECZEMA OF CHILDREN.

The following formula is recommended for eczema of children:

℞ Bismuth subnit.....10 grammes.
Zinci oxyd.....2 “
Glycerini.....8 “
Acid carbol.....gtt xx “
Vaselin. albi.....30 “

or ℞ Bismuth subnit.....20 grammes
Zinci. oxyd.....5 “
Acid. carbol.....2 “
Vaseline albi.....0 “
M. S. Ext. use.

When there is much irritation and itching:

℞ Bismuth subnit.....5 grammes.
Glycerine.....20 “
Acid carbol.....gtt. xij “
Aquæ rosæ.....30 “
M. S. Shake well and apply with a soft brush.

—*Deut. Med. Woch.*

MATISM.

Dr. Hening (*Lo Sperimentale*, No. 18, 1891) praises the following:

℞ Salipyrin.....grammes 6.
Glycerin.....“ 14.
Syrup raspberry.....“ 30.
Ad. destillat.....“ 40.
A teaspoonful every half hour, only taken in the afternoon.

The pains and temperature diminish after the administration of this formula.

STRYCHNINE IN ALCOHOLISM.

Dr. Portugalow (*Lo Sperimentale*, No. 19, 1891) treats all forms of alcoholism with the nitrate of strychnine:

℞ Strychnin. nitrat.....cgms. 6
Aq. destillat.....gms. 15.
For hypodermic use. Inject once or twice daily, first 5 dgms. (7½ ♏), then 25 dgms (37 ♏).

Generally ten to sixteen injections are sufficient. Small doses of the bromide of sodium may be given simultaneously.

WHOOPING COUGH.

℞ Oil of eucalyptus.....grains 6.
Spirits turpentine.....“ 6.
Alcohol.....“ 45.
M. Sig. As an inhalation.

—*Dietetic Gazette.*

RHEUMATOID ARTHRITIS.

Prof. DaCosta prescribed the following treatment for a woman aged forty-five years:

℞ Ammonii iodidi.....gr iij.
Aquæ cinnamon.....f ℥ j.
M. Sig. Three times daily, with massage of the joints affected.

—*Coll. Clin. Rec.*

MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by **postal note, money order** or **registered letter.**

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount **earned, received** and **due** in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

"The Medical and Surgical Reporter" stamped in gilt on the back.

PRICE, 50 CENTS.

PLEASE SEND MONEY WITH ORDER.

LEADING ARTICLE.

UNUSUAL MANIFESTATIONS OF EPILEPSY.

It may safely be asserted that no other disease exists exhibiting such marked typical features as does true or essential epilepsy, which, at the same time, is so infinitely varied in its expression. Many other affections present themselves in varying ways, and often with but one of their characteristic features to enable us to recognize them, but from the typical epileptic seizure it is easy to count hundreds, almost, of other symptoms which clearly point to the same causative pathological state. As an instance of the absence of the chief symptoms of a disease we may point to exophthalmic goitre, in which the bulging of the eyeballs, or the thyroid enlargements may not be present, still we know that we have to deal with the same pathogenesis as if all three cardinal symptoms were clearly and typically observed. In like manner, in epilepsy we may find any of its clinical symptoms absent and still be certain that we have to deal with the same neuropathic disorder.

From time immemorial certain prominent symptoms of epilepsy have been considered as the striking features of the disease, and rightly so, for they are by far the most common and impressive. These could not be more typical: The well-known fall to the ground, preceded or not by cry or aura, complete unconsciousness, succeeded by convulsive contractions of the muscular system, and ending in a deep sleep. These symptoms have been, and are to-day, very generally considered as a *definition* of epilepsy. Where, however, a broader view is taken of all the symptoms which occur of undoubted epileptic origin, it is seen at once that any definition, including simply these standard phenomena, is wholly inadequate.

Let us briefly notice some of the more common modifications of the epileptic paroxysm. First, the convulsive movements may be absent in the attack. This is so in *petit mal*, which all authorities have agreed

upon as being an expression of essential epilepsy. In this form of seizure sudden loss of consciousness is the sole symptom. Convulsions are also absent in many other forms of epilepsy, which will presently be referred to. Loss of consciousness has long been considered one of the cardinal features of epilepsy, but in many cases of local lesion of the brain we know it is absent, and many cases have been reported in which, during the epileptic attack, consciousness was preserved. It may be objected that such cases should not be termed epilepsy, still it must be remembered that cases of local cerebral lesion are often attended by general convulsions, with complete unconsciousness, so that it may be impossible to clinically separate cases in which there is only local convulsions, without loss of consciousness, from cases having the same pathology and attended by general convulsions, with absolute unconsciousness. Therefore, the tendency of the highest authorities upon the subject is to use the term epilepsy, even if the convulsions are limited and consciousness is retained. Again, cases have been recorded in which a subjective sensation has been the only symptom of the attack. Thus, Dr. S. Weir Mitchell reported a case in which a loud sound in one ear was the sole symptom, and classifies the case as purely physical epilepsy. The deep stupor or sleep which usually follows an epileptic seizure may be very variously substituted, but most commonly by excitement, mania, automatic procedures, etc., or it may be very brief, or prolonged for days even, or, finally, it may be entirely absent. Some authorities (particularly English writers) lay stress upon the *aura* as being very commonly present in epilepsy, still all admit its varied character, and that in a large proportion of cases it is wanting. In a large class of cases it may be the main symptom complained of. Especially is this true where it takes the form of sudden and severe local pains in the head or in the cardiac region, in some cases of which the patients will only complain of sudden attacks of pain; thus, upon careful observation, momentary unconsciousness, with convulsive twitchings, more or less general, may be seen, and so lead to a correct diagnosis.

Under the term masked epilepsy a large number of cases have been described by different writers, in which the disease appeared in the form of unaccountable acts upon the part of the patients so afflicted, who afterward remembered nothing of them. These cases of what may be termed *epileptic automatism* are exceedingly interesting, particularly from a *medico-legal* standpoint. Thus, cases have been reported where the patient suddenly becomes unconscious, but is apparently in his normal condition, and may continue his work, or, as in a case reported by Hammond, may travel and transact business for days together, finally suddenly becoming conscious and unable to give any account of his actions. Very interesting cases of this rare form of epileptic seizure have been reported by Bucknill and Luke (*Psychological Medicine*, Ed. IV, p. 337), Legrund du Saull (*Etude Medico-legale sur les Epileptiques*, Paris, 1877), Hammond (*Treatise on Insanity*), Spitzka (*Insanity*), H. C. Wood (*Nervous Diseases*, p. 460), C. M. Hay, M. D. (*Journal of Mental and Nervous Diseases*, June, 1889), and others.

Another form of epilepsy which may properly be classed under the same head is running epilepsy or *epilepsia procurrens*. In this form of attack sudden fits of running, more or less prolonged and violent, may be the sole symptom. It is attended by complete unconsciousness, and if the patient is interfered with in this state, he may be extremely violent and commit any crime, or, as in a case reported by C. M. Hay, M. D., (*Journal of Nervous and Mental Diseases*, N. Y., June, 1889) the attack may assume the form of an ordinary attack of *grand mal*.

In an interesting paper descriptive of many unusual cases of epileptic phenomena, S. Wilks, M. D., F. R. S., consulting physician to Guy's Hospital, London, discusses the question as to whether coma or sleep may be the only symptom of epilepsy. He thinks it may be so, and cites several cases in support of this belief. Doubtless the literature on the subject will strongly prove that periodi-

cal attacks of coma should be classed as an epileptic symptom, of just as much significance as the brief attacks called *petit mal*, or the very varied manifestations classed together as *epileptic automatism*. If we admit that coma may be the sole epileptic symptom in any case, it instantly suggests the question as to the possibility of partial unconsciousness being at times due to the same cause. All are more or less familiar with the queer actions, the dazed condition, and the various subjective sensations which affect many cases of chronic epilepsy, and also with the different mental and physical states which follow fits in such subjects, varying from simple defect of attention to violent mania or profound coma, and from slight paresis to complete, but usually evanescent, paralysis of motor functions. How far these manifestations, when occurring alone periodically, are in accord with our definition of epilepsy is a question which must be considered as partially answered, at least, by many reported cases of unusual epileptic phenomena which have been considered.

The practical side of these states to the general practitioner is undoubtedly from the standpoint of diagnosis and treatment, while to the pathologist they open the most perplexing of problems for reasonable solution. How is it that the same underlying cause can produce such varied symptoms as the ordinary epileptic seizure, attacks in which any of the cardinal symptoms of the disease may be absent, masked epilepsy or epileptic automatic consciousness, periodic coma, running epilepsy, purely physical epilepsy, and attacks of mild uncontrollable epileptic mania? Certainly a completely satisfactory answer is not contained in any one of the numerous and ingenious theories regarding the physical basis of epilepsy, and the disease must still be reckoned among those which are chiefly of *clinical* interest.

A CORRECTION.

The name of the author of the communication in the issue of Jan. 30th, on Gumma of the Iris, is Florence Mayo, not Mays, as published.

BOOK REVIEWS.

COOKERY FOR THE DIABETIC, By W. H. & Mrs. Poole, with a preface by Dr. Pavy. London and New York, Longmans, Green & Co., 1891. Price, $1.00, cloth.

No one will gainsay that a most important part of the treatment of diabetes is in the patient's dietary, and that, as a rule, the afflictions of this class of cases are greatly increased by the intense wearisomeness of the plain unvaried diet to which they are subjected. The authors of this little book have endeavored to give to the diabetic a knowledge of the scientific principles on which the diet is based, and recipes for preparing such articles as come within the special dietetic range, so that they will not only be palatable and pleasing to the eye, but afford sufficient variety to avoid the horrible monotony ordinarially experienced. The book can be highly recommended.

A COMPLETE MEDICAL POCKET FORMULARY, also a special list of new drugs with their dosage, solubilities and therapeutical application; of formulæ for suppositories; formulæ for hypodermic medication; list of drugs for inhalation; tables of poisons with their antidotes; a posological table; a list of incompatibles; table of metric equivalents; brief account of external antipyretics, disinfectants, medical thermometry; urinary tests and much other useful information. By J. C. Wilson, A. M., M. D., physician to the German Hospital, Philadelphia, etc., etc. J. B. Lippincott & Co., publishers, Philadelphia, 1892. Price, $2.00

The number of new formularies that have appeared during the last few years, and the large sale which many of them have had, renders it evident that such works fill a decided want. Besides nearly 2600 formulæ there have been added various matters, as above alluded to, of immediate value in everyday practice.

Whatever Prof. Wilson does he does well, and we can say without hesitation that this latest production of his pen, although but a compilation, is of exceptional excellence, and by far the best work of the kind that has been brought to our notice.

LESSONS IN THE DIAGNOSIS AND TREATMENT OF EYE DISEASES, By Casey A. Wood, C. M., M. D., formerly Clinical Assistant, Royal London Ophthalmic Hospital, etc., with numerous wood-cuts. George S. Davis, Publisher, Detroit, Mich., 1891. Paper, 25 cents; cloth, 50 cents.

This number of the "Physician's Leisure Hours Series" has been prepared for the purpose of aiding the physician to detect and treat, by means always at hand, those diseases

of the eye which experience has shown are most frequently overlooked in the course of general practice; and is more or less in the nature of a supplementary work to several others already published in the same series: Conjunctival Diseases by Prof. Wittendorf, and the Detection of the Necessity for Wearing Glasses, by Prof. St. John Roosa. Several subjects have therefore been omitted which otherwise would have been touched. Dr. Wood has given us a work easily within the range of the general practitioner and is generally of an excellent character.

PERISCOPE.

THERAPEUTICS.

THE USE OF JABORANDI FOR URTICARIA.

I have noticed in some of my medical journals of recent date various remedies recommended for the cure of urticaria. I have not, for the past ten years, used any other remedy than jaborandi for this affection. I give one-half teaspoonful of the fluid extract every half hour until four doses are taken, or until free perspiration or salivation is induced. I usually direct it to be given in the evening, and instruct the patient to avoid exposure to cold while taking it and for thirty-six hours afterward. If necessary, repeat in same way in twenty-four hours. I have in no case had to repeat doses more than once to effect a cure I have also found jaborandi given in the same way a most excellent remedy in gonorrhœal rheumatism, when given in the beginning.—Dr. C. Heaton, in the *Cinn. Lancet-Clinic.*

IPECACUANHA IN ANTHRAX.

Dr. Davies-Colley (*La Sémaine médicale*, No. 51, 1891) has employed ipecacuanha externally and internally in the treatment of anthrax with success. He excises the ulcer, dusts the wound with powder of ipecacuanha root, and administers this remedy internally in doses of twenty-five centigrammes (four grains), repeated every four hours. In five consecutive cases of anthrax he obtained good results by this method, while out of eight cases treated otherwise he had two deaths. Dr. Muskett, a South African physician, who first introduced this method of treatment, treated fifty cases in fifteen years without a single fatal termination. Ipecacuanha added to cultures of anthrax kills the bacteria but does not influence the spores.

FURTHER RESULTS FROM KOCH'S REMEDY IN MINUTE DOSES.

At the 64th Congress of German Naturalists and Physicians Prof. Aufrecht, of Magdeburg, reported 112 cases of tuberculosis with most gratifying results, under, however, much smaller doses than given in Germany last winter. He excluded far-advanced cases from the treatment, and has now 48 cases which are considered cured, 37 cases very much improved, and 22 cases improved, only five cases out of the whole number having derived no apparent benefit.

The treatment was long-continued, beginning with so small a dose as 0.0001 gramme and not exceeding 0.005. The discussion by others who had had experience was favorable to small doses, and a number of successful reports were added.—*Deutsche med. Wochenschrift*, Oct. 8.

PEROXIDE OF HYDROGEN IN TYPHOID FEVER.

Dr. F. H. Wiggin writes, in the *Medical Record*, that having had good results in using preoxide of hydrogen locally in diphtheria and tonsillitis, and in infected wounds, it occurred to him when a case of typhoid fever came under his care, during his summer practice, that this remedy might be beneficial, it being the most powerful non-poisonous germicide we possess. On August 24 he was called to see Abby M—, who gave a history of having been ill for a week with fever and diarrhœa. On examination he found a characteristic case of typhoid fever, with temperature 104½° F.; pulse, 130; sore spots, abdominal pain, tympanites, diarrhœa, and mild delirium. I prescribed one ounce of fifteen volume peroxide of hydrogen to eight ounces of water, to be taken every three hours, by the mouth. On the following day I found the patient more comfortable; temperature, 103° F.; pulse, 112; had had only two movements during the twenty-four hours; less delirium and less pain in head. On the 25th had had one movement; temperature, 102° F.; pulse, 104; less tenderness in abdomen, and pain in head diminishing. On the 27th, temperature, 100½° F.; pulse, 98; no movement, tympanites disappeared, and head, though still weak, clearer. On the 29th, temperature, 99½° F.; no movement. On the 30th, temperature normal; pulse, 84; formed movement. The case now went on uninterruptedly to recover, with nothing further of interest to report. On the 9th of September I discontinued my visits, the patient being discharged cured, though weak.

ILLUMINATION *VERSUS* EXPLORATORY PUNCTURE OF THE MAXILLARY AND FRONTAL SINUSES.

Ziem, of Dantzig, (*Berl. klin. Woch.*, June 15th, 1891) repeats his previously expressed view that the diagnosis of suppuration of the maxillary sinus cannot be made with any certainty by the method of illumination through the mouth. In this view he finds himself in opposition to Bresgen and Vohsen; while, on the other hand, he is supported by Lichtwitz, of Bordeaux, and Srebrny, of Warsaw. Ziem adduces, in the first place, those cases of slight suppuration, where neither the amount of pus nor the thickening of the mucous membrane is sufficient to interfere with the transmission of light. In the second place, the size and thickness of the walls of the antrum are not always the same on the two sides in the same individual; and, moreover, there may be an unusual development in the size of the nasal fossa, with imperfectly developed maxillary sinuses. Both Lichtwitz and Srebrny have demonstrated by actual experiment that illumination could not be relied upon to prove the existence of pus in the antrum. As to the method of making an exploratory puncture, Ziem still maintains that it is best to make an opening through the alveolar ridge, and to send a stream of water thence through the nose. With regard to the frontal sinus, he holds that illumination by itself is not capable of furnishing a means of diagnosis, since here, also, there is much difference in the size of sinuses and the thickness of the walls. He considers, however, that a combination of this with other methods may be useful. At all events, in the next case which occurs in his practice with symptoms of suppuration in the frontal sinus, he would employ illumination; and he would follow this by use of the air douche. He would then use illumination again, and if the transparency of the sinus were now increased that would be an indication of disease of the sinus. On the other hand, if no result followed, the case would still be doubtful, and the question of puncturing the sinus from the outside would present itself. This exploratory puncture is rendered much safer by employing illumination, as Vohsen has shown, for the exact limits of the sinus are thereby defined. Having made a puncture with a small trephine, and injected a stream of water, the presence of pus is at once demonstrated, and the after-treatment can be carried out through this opening, which can be enlarged, if necessary, much more effectually than by endeavoring to blow air or powders through the frontal canal, or by cauterizing the mucous membrane of the nose in the vicinity of the orifice of the frontal sinus.—*Brit. Med. Journal.*

MOVABLE VISCERA.

Dr. Mann (*Deutsch. med. Wochenschr.*, August 27, 1881) records the case of a man, aged 43, who suffered from a severe attack of scurvy. A year later his liver, and ten months afterwards the left kidney were found to be movable. The following year the spleen, too, became floating. These facts were diagnosed clinically, and verified at the necropsy, death having resulted from pulmonary œdema and heart disease. After reviewing the causes to which undue mobility of the abdominal organs has been attributed by various writers, Dr. Mann concludes that the favoring conditions are three: (*a*) increased weight of the organ; (*b*) relaxation of the abdominal wall; (*c*) increase in the capacity of the abdomen.—*Brit. Med. Jour.*

ETHERIZATION IN LARYNGEAL CROUP.

Dr. Betz reports the case of a child, aged eighteen months, that presented the typical symptoms of laryngeal croup. The case appeared so hopeless that tracheotomy was, although proposed, rejected. Dr. Betz then proposed "etherization." Three drops of a mixture of either sulph. 3 parts, acetic ether 1 part, menthol 0.1 part, were ordered to be inhaled every quarter of an hour, just as chloroform is inhaled. It was hoped that the cold from the evaporating mixture would contract the surface blood-vessels of the larynx, and thus reduce the œdema present. The child was seen again in two hours, and the condition had somewhat improved. The etherization to be continued, 3 to 4 drops every half-hour. After six hours the condition was unmistakably better, so much so, in fact, that the etherization could be dispensed with. A piece of intestine filled with ice was placed around the child's neck. After this progress was so rapid that in twenty-four hours the child was out of danger.—*Memorabilien.*

MEDICINE.

PRIMARY TUMORS OF THE HEART.

Dr. Jurgens (*Berlin. klin. Wochenschr.*, October 13, 1891) publishes four cases of primary tumor of the heart—a rare affection, in regard to which knowledge is still limited. Case 1 is that of an infant aged 10 months in whose right auricle was found a growth about the size of a cherry. It took origin between the superior vena cava and the insertion of the anterior flap of the tricuspid valve, and on microscopical examination proved to be a simple fibroma. The endocardium of both ventricles here and there showed some fibrous thickening. No symptoms of heart disease were detected during life. Case 2 is that of a man, aged 50, who, although free from heart symptoms during life, was found *post mortem* to have a polypoid fibro-myxoma of his left auricle. The tumor, as large as a walnut, was attached to the middle of the anterior wall, and hung down an inch and a half into the mitral orifice. Microscopical examination showed the structure to be that of a highly vascular pigmented fibro-myxoma, the pedicle containing some striated muscular fibres. Case 3 is that of a man, aged 36, who, having died suddenly, was found at the necropsy to have suffered from a fibro-sarcoma of the right auricle and tricuspid valve, which caused considerable stenosis of the tricuspid orifice. No other pathological condition was discovered. Case 4 is that of a woman, aged 19, who also died suddenly, and whose heart was found *post mortem* to contain numerous small tumors buried in the wall of the right ventricle. These on microscopical examination proved to be gummata infiltrating almost the whole of the right side of the heart. The endocardium, the septum, and especially the region of the tricuspid valves, were also extensively infiltrated, the tricuspid orifice forming a rigid opening, admitting only two fingers. The walls of the arteries and of some of the veins, of the right ventricle showed well-marked sclerosis, while many arteries lying in the connective tissue new growths were completely occluded.—*British Medical Journal.*

"CEPHALIC TETANUS."

In the *Berliner Klinische Wochenschrift* for Sept. 7th, 1891, is an important paper by Dr. Brunner, of Zurich, on the Pathogenesis Cephalic Tetanus, a subject which is at present occupying some considerable amount of attention. Under the term "cephalic tetanus" this observer includes all those cases of spasms due to wounds in which the site of invasion of the tetanus bacilli lies in the region of the twelve cranial nerves. Owing to the localization of the site of infection and the initial distribution of the tetanic poison, a group of symptoms develop which distinctly separate this condition from tetanus as ordinarially met with. Moreover, the early manifestations of the disease are further modified by the exact position of the injury to the head and by the virulence of the poison, as has been proved by experiments on animals. For these investigations the products of the bacilli were separated from broth cultures by Kitasato's method. Subcutaneous injections of very small quantities of the poison, separated as above, produced precisely the same result as inoculations of pure cultures of the tetanus bacillus—namely, contraction of the facial muscles on the side on which the injection was made as an initial symptom. Dr. Brunner divides cases of cephalic tetanus into two classes: (1) Cases without paralytic symptoms; (2) cases with symptoms of paralysis. He does not think that the first class should be considered as cases of ordinary tetanus, for in the latter local spasms are extremely rarely met with, whilst they form the characteristic symptom of cephalic tetanus, and, further, these spasms are often confined to the regions of the cranial nerves, and do not spread and become general. In regard to the second class of cases, in which paralytic symptoms appear, he subdivides them into two groups—one in which the muscles supplied by the facial nerve only are implicated, and a second in which the other cranial nerves are affected. Dr. Brunner draws attention to the fact that a contraction of the muscles on the injured side first appears, and that this gradually gives way to a paralysis. Whether the paralysis is directly caused by the tetanic poison is doubtful. It would seem from experiments that the poison produces its effect locally, and then is carried by the blood current to the brain, and affects the nervous centres. When injected in small quantities locally, it produces spasms of the neighboring muscles, but in larger doses paralytic effects ensue in the same region. Dr. Brieger considers that this is a direct result of the tetanotoxin, but Dr. Brunner does not think that this has been proved. Paralysis and spasms occur when trigeminus has been previously divided, so that any action along the sensory tract is excluded. By injecting the poison into the cerebral hemispheres of rabbits, facial spasms are produced on both sides. If an animal be inoculated with the tetanic poison, and the motor

nerve endings be paralyzed with curare, the facial spasms disappear completely. This demonstrates that the tetanotoxin can act directly upon the motor nerve endings. Dr. Brunner thinks that it is possible that the fibrillæ of the striped muscles are likewise damaged by the poison. The muscles concerned in the act of swallowing are sometimes affected in cephalic tetanus, but not so often as when the wound is situated in some part of the body other than the head.—*Lancet.*

ULCERATION OF THE MOUTH AS A SYMPTOM OF LEAD POISONING.

Dr. Osmund Stedman, has recorded a few notes on this subject because it does not seem to be mentioned in the ordinary text-books as one of the symptoms of lead poisoning. His attention was first directed to ulceration of the mouth as a symptom in this disease by a friend who had two cases in one family, both children, who each had a crop of small ulcers in the mouth, and on having the drinking water analyzed it was found to contain a considerable trace of lead. In April of this year he was called to see a child about two and a half years of age, which was feverish, temperature 100.4°, and had six or eight small ulcers in his mouth which are best described as "phlyctenular." They were situated on the inner sides of the cheeks, some opposite to where there were teeth, and some further back, so that they did not appear to bear any relation to the teeth. The ulcers consisted of red excoriated spots varying in size from that of a pin's head to that of a hemp-seed, each surrounded by a small halo of whitish swollen mucous membrane. The child was constipated, and except the fever had no other symptom to note. The following day the child vomited several times, and had frequent attacks of griping pain in the abdomen (colic), during which he screamed and drew up his legs. These symptoms, of course, clearly pointed to lead as the cause of the trouble, and on analyzing the drinking water it was found to contain a considerable trace of lead, the source of the contamination being rain water stored in a lead-lined tank. There was no blue line present at any time, and on removing the cause of the trouble the patient rapidly got better, the treatment being directed to relieve the constipation by enemata, and the colic by small doses of opium. It would seem, therefore, that in cases of ulceration of the mouth in children one should look carefully for lead poisoning as a possible cause.

THE PRODUCTION OF IMMUNITY AGAINST AND THE CURE OF PNEUMONIA.

In 1890 was published the important discovery by Behring and Kitasato that blood serum taken from animals that had been rendered immune to tetanus and diphtheria was capable of curing other animals suffering from those diseases. Drs. G. and F. Klemperer (*Berliner klinische Wochenshcrift*, August 24th and 31st, 1891) publish a research carried out in regard to pneumonia, with the object of discovering how immunity against the pneumococcus could be best produced, whether recovery from the disease rendered an animal immune, and whether it was possible to cure pneumonia by the blood serum of animals that had recovered from the disease. Their experiments, which were confined to rabbits, revealed that every nutrient medium in which the pneumococcus has been cultivated will, if inoculated, render an animal immune against pneumonic septicæmia, even after the cocci have been removed by filtration. The power of producing immunity is more speedily acquired, and is increased if the infected nutrient medium (before or after removal of the cocci) is exposed to a temperature of between 41° to 42° C. for two or three days, or of 60° for an hour or two. In every case, however, it was found necessary that some interval (varying from three to fourteen days) should elapse between the inoculation and the production of immunity. Hence it was too late to cure a diseased animal or even to prevent the onset of an attack if the injection was given simultaneously with the outbreak of the disease. On the other hand, serum taken from animals enjoying immunity was found able, especially when introduced directly into the circulation, to cure pneumonic septicæmia. The serum was injected twenty-four hours after infection, while the animals had a febrile temperature of between 105° and 106.5° F. Eight cubic centimetres were injected with the result that the temperature gradually sank during the next twenty-four hours. In twelve successive cases a successful result was obtained. This research therefore confirms, in regard to pneumonia in rabbits, what Behring and Kitasato did for tetanus and diphtheria. Drs. Klemperer next studied the question how the blood serum of an immune animal cures an attack of pneumonic septicæmia, and discovered that when the pneumococcus is introduced into the body of an animal it generates a poisonous substance which can be isolated, and to which the name of "pneumotoxin" has been given. This

pneumotoxin sets up a febrile condition which lasts several days, after which another substance is found to have been produced called "antipneumotoxin," which is able to neutralize the pneumotoxin. The serum taken from an immune animal contains this antipneumotoxin, and it is by means of this substance that it cures an attack of pneumonic septicæmia in other animals. The relation of pneumonia as seen in rabbits with that met with in man was next investigated, and the conclusion arrived at that the disease in both cases is produced by the pneumococcus, but that the human body is much less susceptible to the latter than the rabbit is. Thus it was found that serum taken from pneumonic patients after the crisis could cure pneumonia in rabbits; moreover, pneumotoxin and antipneumotoxin were found to be present in human serum as in that taken from rabbits. The crisis of pneumonia, according to Drs. Klemperer, takes place as soon as antipneumotoxin is produced in sufficient quantity to ueutralize the pneumotoxin. Why immunity against further attacks lasts so short a time in man is still uncertain, but possibly less antipneumotoxin is formed in man than in rabbits in proportion to the pneumotoxin. Some attempts have already been made to cure patients suffering from pneumonia with the help of antipneumotoxin, but further observations are necessary before results can be published.—*Brit. Medical Journal.*

EXPERIMENTAL TYPHOID FEVER.

Gilbert and Girode (*Le Mercredi Medical*, May 6, 1891) call attention to the fact that animals inoculated with Eberth's bacilli have behaved differently in the hands of various experimenters. Gaffky observed no pathogenic action. Sivotinni and others have observed an acute septicæmia without multiplication of the bacilli, while Frænkel and others have observed a disease closely resembling human typhoid fever. The writers detail experiments on two guinea-pigs inoculated with Eberth's bacilli. Both animals had diarrhœa and loss of flesh, and died, one on the fourteenth the other on the thirty-second day. The *post-mortem* examination showed inflammation of Peyers' patches and ulceration of the mucous membrane of the cæcum, with enlargement of the lymphatic glands.

Bacilli were found in various situations. Tubes inoculated with splenic pulp and contents of the intestine showed growths of Eberth's bacilli—*Univ. Med. Mag.*

SPECIFIC GRAVITY OF THE BLOOD IN DISEASE.

Questioning the reliability and practicability of the methods of determining the specific gravity of the blood that have hitherto been employed, Schmaltz, of Dresden, has adopted the pyknometric method as the most exact. For this purpose he employs capillary tubes of special form, with a capacity of about one-tenth of a cubic centimeter. In one case the specific gravity of the blood obtained by venesection, taken with a large instrument, was 1040.98, and with the capilliary instrument 1041.48. As a result of 55 examinations of his own blood, and of examination of the blood of 20 persons of both sexes, Schmaltz has found that the density of the blood is very little, if at all, influenced by taking food or fluids (including a quart of physiological salt solution), by intense bodily exertion, and the development of hyperæmia of the skin at the point from which the blood is to be drawn. The specific gravity of his own blood was somewhat higher in the morning than later in the day, the greatest difference being included between 1056 and 1062.1, and being apparently independent of food and drink. The average specific gravity of the blood of eight men was 1059.1, and of 12 women 1056.2, showing a lower range for women than for men. The specific gravity remains fairly constant in healthy persons.

Schmaltz has tested the specific gravity of the blood of 95 patients, mostly women. 29 were chlorotic women with anæmia, more or less acute, without known cause. In nine of these the specific gravity of the blood fell below 1040, and in two below 1035. In the remaining 18 cases the specific gravity ranged from 1035 to 1049.

In 21 cases existing anæmia was known to have been a result of hæmorrhages and severe blood diseases. The figures obtained were higher than in the case of the chlorotics; two patients died; one had leukæmia and endocarditis (sp. gr. 1034), and one septicæmia and endo-carditis (sp. gr. 1030). In one case of hæmatemesis, the specific gravity was 1031; in one of carcinema of the stomach and liver, 1039, and in one of incipient phthisis it was 1036. On the other hand, in a case of severe metrorrhagia, in which the patient, who a short time before the blood was examined almost died in collapse from hæmorrhage, and was extremely anæmic, the specific gravity of the blood was 1042. In the other cases—heart disease, Bright's disease, typhoid fever, etc.,—the specific gravity ranged from 1039 to 1049.

In a series of 33 cases, including one very anæmic patient, all of the organs of whom were healthy, cases of dilatation and of ulcer of the stomach, tertiary syphilis, progressive phthisis, valvular lesions of the heart, diabetes, marasmus, articular rheumatism, and two convalescent cases, one of pleurisy with effusion, and one of acute bronchitis, the specific gravity of the blood suffered no material diminution, and in two or three cases was even abnormally high—1063 (progressive phthisis and heart disease). Some of these cases lend support to the view of Oppenheimer, that when the proportion of hæmoglobin and the specific gravity are normal, though the patient be anæmic, there must be an abnormal distribution of the blood. It must be borne in mind that in some cases the specific gravity of the blood rises during inanition. In other cases, conditions of blood-stasis, such as occur in phthisis and in heart disease, raise the specific gravity in the areas of stasis.

In 26 cases Schmaltz compared the specific gravity of the blood with the percentage of hæmoglobin and with the corpuscular richness of the blood. He found that a lowering of the specific gravity goes hand-in-hand with a diminution of hæmoglobin, while the specific gravity is in a large degree independent of the number of red blood-corpuscles.

In four cases of chlorosis cured, the specific gravity rose until it became normal; in other cases it increased, but failed to reach the normal without the disappearance of the other symptoms.

As a result of his studies, Schmaltz formulates the following conclusions: Under normal conditions the specific gravity of the blood in man varies within narrow limits; as a rule it diminishes considerably in anæmic conditions, especially in chlorosis and diseases of the blood proper; the density of the blood is chiefly determined by the quantity of hæmoglobin present, while it is in a large measure independent of the number of red blood-cells; with improvement in the anæmic condition the specific gravity of the blood raises, and with complete recovery attains the normal. It seems, therefore, that the specific gravity of the blood is an accurate index of the condition of the disease; when the circulation is retarded in the extremities—for example, in diseases of the heart and lungs—the specific gravity of the blood is not rarely elevated, and may, in spite of persisting anæmia, be found normal.—*Deutche med. Wochenschrift*, Nov. 16, 1891.

[Schmaltz describes his "capillary pyknometer" and his method of using it in the *Ditches Archiv für klin. Medicine*, Bd. xlvii, 145. A capillary tube containing distilled water is weighed, the water is expelled and the tube again weighed—the difference in weight, of course, is the weight of the water. In the same way the weight of a capilliary tubeful of blood is obtained. The weight of the blood and the water being thus known, simple division gives the specific gravity.]—*News.*

SURGERY.

THE TREATMENT OF INTESTINAL OCCLUSIONS BY THE EMPLOYMENT OF THE CONSTANT OR GALVANIC CURRENT.

This has been the subject of a report to the Académie de Médecine, by M. Semmola, of Naples, given in *Le Progrès Médical* for October 3d, 1891, from which it appears that:

"1. There may be an intestinal occlusion caused solely by a defect of enervation.

"2. The curative effect of the constant current is, in such cases, very remarkable."

A case of obstinate constipation in a lady about fifty years of age, under the care of the writer, presented all the symptoms of intestinal occlusion. Large doses of active cathartics were given without success. Thirty grains of calomel at one dose brought no change. At the suggestion of the late Dr. Joseph C. Hutchison, who was called in consultation, a large dose of metallic mercury was given and massage employed in the hope of removing the obstruction without effect. On the sixteenth day the interrupted or Faradic current was used; the negative, through an olive-shaped electrode, was applied within the rectum; the positive, over the abdomen. On the eighteenth day the obstruction was removed, and a copious evacuation gave almost instant relief. The recovery was perfect.

For further details, see article on "Intestinal Obstruction" in the *International Medical Annual* for 1890, p. 333.

A NEW FORM OF SUTURE.

Opossum tail sutures are coming into vogue in America. The tail of this animal has many long and strong fibres, which, according to H. O. Marcey, of Boston, assumes the purposes of ligatures much better than catgut. From observations which he had made in cases in which he used the kangaroo tendon. he found that the tendon had not been absorbed or encapsuled, but had become part of the living tissue. He had often availed himself of the opportunity to prove this fact in the case of vessels which some time previously he had tied with the tendon.—*Med. Press.*

THE ETIOLOGY, PROPHYLAXIS AND THERAPEUTICS OF HÆMORRHAGES AFTER TONSILLOTOMY.

Although hæmorrhages following excision of the tonsils are of rare occurrence, they are of great interest to surgeons. The majority of patients are adults, in whom the hæmorrhage is due to the fact that the incised blood vessels fail to retract and contract properly in the indurated tonsillar tissues. The bleeding never results from injury of the carotid artery, as was formerly believed, but comes from the enlarged tonsillar branch of the carotid or the ascending pharyngeal, from the pterygo-palatine artery, or from the ascending palatine in cases where the latter vessel is abnormally situated. Usually, however, the hæmorrhage is not arterial, but of parenchymatous character. It can be easily understood that in persons suffering from hæmaphilia, tonsillotomy may give rise to an uncontrollable hæmorrhage.

As regards the prophylaxis, care should be taken in the performance of tonsillotomy not to draw the tonsils too far forward between the faucial pillars, because the surrounding folds of mucous membrane, and the vessels at their point of entrance in the tonsils, are exposed to injury. These accidents are most likely to happen if guillotine-shaped tonsillotomes or scissor-formed instruments are used. Especial care should be taken not to operate in the acute stage of inflammation, or in marked tonsillar hypertrophy, because these conditions favor the occurrence of secondary hæmorrhage. For the same reason the surgeon should content himself with excising only that portion of the tonsil which projects beyond the faucial pillars, the more so since the remaining part usually undergoes spontaneous shrinkage.

If a severe hæmorrhage occurs we should make use at first of styptics, which, in conjunction with compression, are usually sufficient to arrest the bleeding. The application of ice is an excellent hæmostatic. If these means fail, we resort to cauterization with nitrate of silver, or better still, the Pacquelin cautery. In the severe cases litigation of the common carotid artery has been successfully performed. As a final resort, tracheotomy with tamponing of the pharynx may be entertained. Experience has shown that severe hæmorrhages are frequently arrested by the occurrence of vomiting or syncope, and these conditions may be artificially produced for the same purpose.—Dr. O. Von. Holst, in *Oest.-ungar, Centralbl f. d. Medicin. Wissenchaften*, No. 11, 1891.

THE METHODS OF CARRYING OUT ASEPSIS IN VON BERGMANN'S CLINIC.

Schimmelbusch (*Langenbeck's Archiv.* Bd. 42) gives in detail the manner in which the dressings, instruments and brushes used in the clinic of Von Bergmann are rendered aseptic. The use of sublimate and carbolic solutions has largely given way to the employment of moist and dry heat. The efficiency of antiseptic solutions has been overestimated. It has been shown that threads infected with splenic fever contained living germs after fourteen days' immersion in a five per cent. carbolic solution, also that they were not killed by an immersion in a 1 to 1,000 sublimate solution for twenty minutes; they lived even after twenty-four hours' immersion. The antiseptic property of a solution may be destroyed by the active agent being rendered inert by undergoing a chemical change; thus, sulphur (as in fæces) will combine with corrosive sublimate and from an insoluble and inert sulphide of mercury. La Place has also shown how albuminous compounds will combine with it and thus destroy its activity. It is also impossible to subject each individual bacterium to the action of the germicide. Bacteria often occur in masses or in extraneous matter, and it is only those on the surface that are reached and affected by the antiseptic. Oils and fats likewise interfere with their action. These facts, together with the dangerous action of antiseptics on the human organism, contrast markedly with the efficacy and innocuousness of disinfection as accomplished by moist and dry heat. Mechanical cleansing is at the basis of and should precede all attempts at sterilization.

It's bad enough to have a cold,
And yet one might endure it,
If every fool would not proceed
To tell one how to cure it.—*Ex.*

TREPHINING THE VERTEBRAL COLUMN IN GUNSHOT WOUND OF THE SPINAL CANAL.

At a meeting of the Société de Chirurgie on November 18 (*Sem Méd.*, November 25), M. Nicaise presented, on behalf of M. Vincent, of Algiers, a communication on gunshot wounds of the spinal cord, and the treatment of them by trephining the spine. He classifies the lesions in such cases as follows: (1) Simple compression of the cord by effused blood, splinters of bone, or fragments of the projectile; (2) contusion or laceration of the cord caused by the bullet; (3) lodgment of the bullet in the vertebral column, with or without projection into the canal. M. Vincent is an advocate of operative interference in such cases, and he reports eight cases, with five cures and three deaths. He considers the cases in which the lesion belongs to the first of the above-mentioned categories as being the most favorable for operation, and he relates, in illustration, the case of a man, aged 31, who was struck by a bullet in the lumbar region. This was followed two days later by marked signs of compression of the cord. M. Vincent cut down and found a fractured lamina; he trephined, and introducing his finger into the canal found the cord free from compression. The bullet could not be found, and the wound was closed. Symptoms of meningo-myelitis followed the operation, but they quickly passed off, and in three weeks the patient was able to walk. Where the lesions come under one of the other categories mentioned, surgical interference is also indicated, but it is most important first to detemine as far as possible the exact site of the injury. He related the two following cases: 1. A lad, aged 18, was struck by a revolver bullet in the dorsal region; this was followed by symptoms of bruising of the cord. The spinal column was trephined on the third day, and the bullet was extracted. Death occurred eight days later, when it was found that the cord had been completely crushed. 2. A man, aged 37, was shot in the back on the level of the tenth dorsal vertebra; complete paraplegia followed. The bullet, together with a splinter of bone, was removed. After a period of improvement the patient died on the ninety-fourth day. M. Lucas-Championniere said that the difficulty in these cases lay in the localization of the lesions. He had trephined the spine, though not for gun-shot wound. He considered the operation as being still outside the exact rules of surgical art, besides being long and laborious, but he thought it capable of yielding good results, and the aggravation of the paralytic symptoms which sometimes ensued was merely transient. M. Bazy said he had three times operated on the spine, always using the chisel and mallet. In one of his cases the paralysis was so extensive that the patient breathed entirely with his diaphragm; nevertheless, chloroform was given without bad effect. M. Moty said he had made a *post-mortem* examination in the case of a patient from whom M. Delorme had removed a portion of a vertebral arch. The gap was filled up by fibrous tissue.—*Brit. Med. Jour.*

SIXTY-TWO CASES OF ENUCLEATION FOR GOITRE.

Lehotzky in the *Wiener klinische Wochenschrift*, October 8, 1891, gives the histories of a large number of operations by enucleation for enlargements of the thyroid gland from the clinic of Albert. He says the operation has definitely demonstrated its worth for a certain class of cases. Kocher, Wölfler and König are quoted as supporting this view. The operation is based on the fact that one of the forms of hypertrophy of the thyroid gland consists of an enlargement of a few of the follicles of the gland separated from the healthy parts by a more or less thick layer of fibrous tissue. It is not intended for other forms of enlargement or when the whole of the gland is affected. It is undertaken sometimes on account of the discomfort which the increased size occasions and sometimes for cosmetic reasons. The size of the growths varies from that of a hazelnut to that of a man's fist. The parenchymatous capsule of the nodes varied in thickness, one reaching five centimetres. Their boundary, was, in most cases, sharply defined. Sometimes, instead of being able to enucleate with blunt instruments it was necessary to cut and ligate carefully. The most dangerous thing in the operation is hæmorrhage. Capillary and venous hæmorrhages occur if the enucleation is made slowly, while, if made rapidly, very free arterial and venous hæmorrhage may occur. In such cases the wound is tamponed with iodoform gauze, and this is gradually removed as the vessels are ligated, all bleeding being carefully stopped. While in many cases the bleeding was enormous, still it was always controlled by ligature. Dividing the tissues between ligatures lessens the loss of blood, but prolongs the operation, and requires great patience. Parenchymatous hæmorrhage was only noticed in one case, also secondary hæmorrhage once. In one case the hæmor-

rhage after enucleation was so free as to require ligation of the carotid. One death from entrance of air into a torn vein is recorded. Enucleation is also suitable in cystic goitre, and where from the thinness of the cyst-wall or other causes it is impossible to remove all the cyst-wall, it may be sewed to the wound and treated with iodine injections. The same may be done with suppurating cysts. Chloroform narcosis was employed in most cases, although in small-sized growths cocaine anæsthesia was sometimes successfully used. One death occurred from chloroform. The incision should be made from above downward over the most projecting part of the growth. Catgut ligatures and silk sutures were employed and iodoform gauze packing to stop bleeding, the strip being allowed to hang out of the lower angle of the wound. Several cysts or nodes can be enucleated through the same wound. The recurrent nerve lies out of the plane of operation and can be avoided. In many cases the operation is readily done and heals promptly. Enough glandular tissue is left behind to obviate all fear of any cachexia following. When the growth is very large, and composed of several parts, so much only is taken away as will remove the bad symptoms of the case.—*Univ. Med. Mag.*

RELATION OF ALBUMINURIA TO SURGICAL OPERATIONS.

In a paper upon this important theme read before the Southern Surgical and Gynæcological Association (*Virginia Med. Monthly*, Dec., 1891), Dr. Long arrived at the following conclusions:.

1. Ether or chloroform rarely injures healthy kidneys.

2. When renal disturbances occur from the use of an anæsthetic, the kidneys being healthy, they are due rather to prolonged narcosis, exposure of the patient, or perhaps to the combined influence of the operation and the anæsthetic.

3. A mild degree of albuminuria (or nephritis), especially if recent, is not a contra-indication to the use of chloroform.

4. Even in the presence of advanced and extensive renal changes, an anæsthetic may be employed, provided the patient or the family be advised of the additional risk.

5. Of the two anæsthetics usually employed, it is yet a mooted question as to which is the safer, so far as the kidneys are concerned, unless it be in obstetrical operations.

6. While it is by no means the rule, profound functional disturbance, and even organic lesions may be induced by an operation, apart from the influence of the anæsthetic.

7. Such renal changes are due to reflex sympathetic action, or to sepsis, or both.

8. Operations in certain regions—notably, the abdominal, genito-urinary, anal, or rectal, are especially liable to produce renal complications.

9. A healthy condition of the kidney *minimizes*, but does not obviate, the danger referred to.

10. Albuminuria is always an indication of renal lesions, and should be regarded with distrust, but is not a positive contra-indication to an operation.

11. When albuminuria is associated with other evidences of advanced renal changes, no operation should be undertaken without candidly stating to the patient or friends the dangers incident to the condition of the kidneys.

12. Paradoxical as it may seem, an operation will sometimes relieve an albuminuria due to acute affections.

13. No surgeon is justified in undertaking an operation without first knowing the state of the patient's kidneys.

THE LOCAL APPLICATION OF ETHER IN STRANGULATED HERNIA.

Finkelstein (*Berliner klinische Wochenschrift*, May, 1891) again draws attention to his method of treating this affection. In 1882, in No. 30 of this journal, he gave the details of sixty-three cases of hernia in which taxis failed. Local etherization was followed by reposition in fifty-four and failed in four; two of these were operated on, and two refused interference and died. In the present paper twenty-three additional successful cases are given, some of which occurred in the practice of other surgeons. In one case improvement occurred, and a movement of the bowels took place, but an operation was afterward performed, and some omentum replaced. Another case died suddenly, and the intestine was found of a dark, brownish-blue color, but strong and not at all easily broken. His method consists in placing the patient on his back, with the hips somewhat elevated and the knees flexed. The scrotum is to be supported by a small pillow. Every ten or fifteen minutes a drachm of sulphuric ether is poured on the tumor, and in from three-quarters to three hours usually, or six hours, as occurred in one case, the tumor will have diminished in size, and will either recede of itself or be readily returned.

The surrounding parts may be partly protected by smearing with oil, or a flat layer of cotton may be placed on the tumor and the ether poured on this.—*Univ. Med. Mag.*

OBSTETRICS.

CÆSAREAN SECTION FOR ECLAMPSIA OF PREGNANCY.

Dr. H. Von Swiecicki (*Der Fraaenorzt*, September, 1891) performed Cæsarean section on May 25th, 1891, in a small house in the city of Posen. The patient, in the last stage of pregnancy, was in a profound coma, interrupted occasionally by tonic and clonic convulsions. The legs were œdematous. There was no physical sign that labor had commenced. On that account Dr. Swięcicki determined to operate at once. The abdomen was thoroughly washed. A free incision was made in the median line, beginning above the umbilicus and ending about two inches and a half above the symphysis. When the peritoneum was opened the operator enlarged the incision till the uterus could be extruded without difficulty. The assistant pressed the parietes together behind the uterus, the intestines being protected by folds of mull. An elastic ligature was passed round the uterus close to the cervix. The uterus was laid open in the middle line, which was the site of the placenta. The child, placenta, and membranes were carefully removed. The child was asphyxiated and could not be revived. The uterine wound was closed with twenty-two asepticised silk ligatures. The deep sutures were passed designedly through the decidua. Dr. Swiecicki had successfully performed Cæsarean section for a case where labor was obstructed by a bony tumor of the pelvis, and found that it was best to include the decidua; nor did a very careful apposition of the serous surfaces of the wound appear essential to success. During the application of the sutures the assistant rubbed the surface of the uterus up and down. The elastic ligature was now removed; it had not been tied very tightly lest it should paralyze the vasomotor nerves and cause atony of the uterus. There was slight bleeding from two suture tracks, which soon ceased. The uterus contracted well and was returned into the abdomen. The abdominal wound was closed. The operation lasted scarcely thirty minutes. The coma continued after the operation and symptoms of œdema of the lungs quickly followed. The patient died. This is the tenth case where Cæsarean section has been undertaken for eclampsia, as advocated by Halbertsma. No fewer than six were performed in Holland; out of these five mothers recovered and five children were saved. The convulsions ceased in four of these cases; in the fifth three slight fits occurred after the operation. Case 7 was Herff"s; mother and child were saved, though the former had jaundice and maniacal delirium before she recovered. Rosthorn and Müller (cases 8 and 9) were as unfortunate as Dr. von Swiecicki, who on that account cannot feel enthusiastic about the grave proceeding in question, since the danger is greater than Halbertsma might induce one to believe. Yet Dr. von Swiecicki considers that in eclampsia near term when the child is alive and cannot be delivered by the natural channel, either owing to entire absence of any natural effort to deliver it or to pelvic obstruction, Cæsarean section is justifiable. The obstetrician must deliberate on the grave responsibility, but the operation must be done as early as possible.—*Brit. Med. Jour.*

PROTECTION OF THE PERINEUM.

Wm. S. Gardner (*Journal of Gynecology*, September, 1891) writes that the value of a complete perineum is so great that the gynæcologist spends much time inventing new methods for its repair. What he has to offer on this subject is only the method of applying the principle that time is the great perineal protector, bearing in mind that almost any perineum will distend sufficiently to allow the safe passage of the head, if only the head can be prevented from advancing with too great rapidity just during the last portion of the second stage of labor. The two great forces driving the child toward the outer world are the contractions of the uterus and the contractions of the abdominal muscles. There comes a time in the labor when the perineum has become so weakened by distention that it can no longer bear the great pressure of these combined forces, a time when a few minutes' delay means the prevention of a rupture. Uterine action is beyond our control; the contraction of the abdominal muscles can be controlled either by complete anæsthesia or by the will of the patient. She is instructed in the interval between the pains that when she feels a pain coming on she is at once to open her mouth and breath through it as rapidly as possible. In addition the head is held back by pressing against the perineum in the direction of the pubes. The perineum should be as carefully guarded during the passage of the shoulders as during the delivery of the head.—*Univ. Med. Mag.*

TO DETERMINE PREGNANCY.

Dr. W. R. Lowman (*Med. Summary*) gives the following method: Examine under the tongue for two teats, about the size of No. 4 shot, each attached to a slender cord in which a nerve runs, connecting with the genital centre. They are pale in the non-pregnant, but in the enciente they are purplish red.

MATERNAL IMPRESSIONS.

Dr. Archibald Mackay writes in the *Lancet:*

I have read with much interest the remarks on Dr. Lee's cases of maternal impressions in the *Lancet* of the 21st ult. As I have met in my practice with several cases in which marks on the child have been ascribed by the mother to fright or other causes experienced during pregnancy, the following notes may be of interest:

The first case which came under my observation was that of a young girl with an oblong patch of soft dark hair on the left cheek, extending from the ear downwards to the neck. The mother stated that while pregnant she was working in the field at haymaking, when her husband threw a young hare, which he had found in the hay, at her, striking her on the cheek and neck in the exact place where the patch of hair was found on the child at birth. The color and character of the hair on the patch closely resembled the fur of a very young hare.

The second case was that of a lady who, on entering her kitchen when pregnant, found the servant with a paraffin lamp on fire. She happened to place her hand on the back of her neck at the moment, and turned away immediately, lest the shock might produce a miscarriage. The child (a male) was born at full time, and when examined had a red discoloration of the skin on the back of the neck, extending upwards toward the occiput, in pointed tips, not unlike a flame in shape and appearance.

The third was also a male child. The mother, immediately after the child was dressed, inquired if he had any marks. I asked her to tell me what kind of a mark she expected, and where I was to look for it. She replied, "Look on the top of the head for a mouse mark." When the head was examined a brown oval patch was found on the spot indicated. The mother in this case did not see the child, and the mark was not observed until she had made inquiry about it. It seems that when pregnant, on opening a press, a mouse jumped out at her feet, causing a sudden shock, and she involuntarily placed her hand on the top of her head in the exact spot where the patch was found on the child.

The fourth case, a male child, when born had a raised bluish mark on the mucous membrane of the lower lip. The mother said she could only account for it by her having great sympathy with a friend who was in bad health at the time she was pregnant, and who had a venous nævus on the lower lip in the same place as on the child's lip.

The fifth case was that of a female child, with a circular pinkish mark on the left arm above the elbow. The mother ascribed the cause to ungratified desire. When walking past a gentleman's grounds she saw a flowering rhododendron, which she stood to admire, and happened to catch her left arm above the elbow with the right hand, being about five months pregnant at the time, and to this cause she attributed the mark on the child.

In these cases the first three were attributed to sudden fright, the part touched at the moment the shock was received being the part affected in the child; the fourth to sympathy, and the fifth to a wish ungratified. The exact period of gestation at which the impressions were received I have not been able to find out, but, as far as could be ascertained, it was between the fourth and sixth months. The mothers in all these cases were strong and healthy, and the infants well-developed and born at full time.

HYDRASTIS CANADENSIS IN OBSTETRICS.

Bossi, of Genoa (*Nouvelles Archives d'Obstét. et de Gynéc.*, Aug., 1891), has carefully analyzed sixty-four cases where he has administered this drug. He finds that the fluid extract, administered at any stage of pregnancy, in doses of 100 to 200 minims daily for several days, has no evil effect either on the mother or child. It is equally innocuous during delivery. It has a constant, curative, and prophylactic hæmostatic action on the uterus during pregnancy, labor, and the puerperium, without any ecbolic effects or modification of the uterine contractions. It is infinitely preferable to ergot, and much less dangerous when distributed to midwives for use in hospitals and in private. Bossi gives 100 to 150 minims daily, in three doses, during hæmorrhage in pregnancy and labor. He also administers it as an immediately curative agent in flooding during labor, in three or four doses amounting to 200 minims; and in placenta prævia he gives the drug at the beginning of labor, and during dilatation of the os. Bossi also uses the liquid extract as a prophylactic agent against *post-partum* hæmorrhage, and against flooding in hy-

dramnios, uterine inertia, large fœtus and placenta, anæmia in the patient, and predisposition to flooding from any known or unknown cause, as proved by the experience of previous labors.—*Brit. Med. Jour.*

GYNÆCOLOGY.

ELECTRICITY IN METRORRHAGIA.

Boer, (*Norsk Magazine for Laegevidenskaden, No. 5, 1891*), in two desperate cases of metrorrhagia, where all other means failed, succeeded by the induction current in stopping the hæmorrhage in the course of ten minutes. it returned after two days, it was again ployed, four times in all, after which the emorrhage ceased entirely.

RACEMOSE SARCOMA OF THE CERVIX.

Pfannenstiel (*Centralbl. f. Gynäk.*, October 17th, 1891) describes a case of the very malignant racemose tumor of the uterus, first described by Pernice as myosarcoma strio-cellulare u ri, and sometimes termed rhabdo-myosarcoma uteri. In Pfannenstiel's case the patient was 53, and been pregnant four times. Five years after the menopause she was seized with sacral pains and discharge. A grape-like mass reached the vulva, occupying the vagina and springing from the anterior part of the cervical canal. This mass was cut away. In one year and three-quarters the patient returned, and the racemose mass, which had grown again in spite of cauterization of the cervical canal, was removed. The wound left on its removal was scraped with the sharp spoon and touched with Paquelin's cautery. Six months later the tumor had recurred. The uterus was extirpated and the patient recovered. Half a year later another recurrence took place in the left half of the vaginal scar. The recurrent growth was cut out and the wound cauterized. When the report was read, recurrence had once more occurred. Pfannenstiel has collected eleven cases of racemose sarcoma of the cervix. It is most frequent in multiparæ, and prevails either at puberty or the menopause. It is essentially malignant, the average duration of life being under two years. After excision, it rapidly recurs in the cicatrix, but is relatively slow in infecting the neighboring parts. The disease has always hitherto recurred after operation. Pfannenstiel believes, however, that this evil record is due to the fact that it has never hitherto been diagnosed until it has formed a large mass. The results of operation will doubtless be less serious when interference can be made earlier. In any case where racemose sarcoma is diagnosed the uterus should be extirpated or, if the disease has advanced too far, the mass must be cut away and the wound freely scraped. The pathological peculiarities of the tumor are perhaps better known than its clinical course. It often contains embryonic striped muscle cells. Owing to its racemose character it is easily distinguished, but it might be confounded with hydatid chorion or with cauliflower ephithelioma of the cervix.—*Brit. Med. Jour.*

TREATMENT OF SEVERE PROLAPSUS UTERI.

Dr. Richelot (*Union Med.*, October 3d, 1891), advocates extreme measures in cases of prolapsus which recur after colpo-perineorrhaphy or Alexander's operation. Vaginal hysterectomy, Dr. Richelot maintains, is a very easy and mild operation. He has twice had recourse to it with success. He adds, however, that though this extreme proceeding is very useful in relieving the patient from the inconvenience of a heavy uterus, it does not prevent the vaginal walls from prolapsing again. Hence hysterectomy must be considered rather as a preliminary operation. Ultimately a colporrhaphy will be needed, or an operation for obliterating the vagina after Le Fort's method. "When that has been done," says Dr. Richelot, "your patient will be thoroughly cured, without possibility of recurrence."—*British Medical Journal.*

ON VAGINAL HYSTERECTOMY FOR CARCINOMA.

So much has this operation been decried on the ground of failure to radically cure, that the latest batch of statistics from Leopold's Klinik, in Dresden, will be received with peculiar interest. A carefully conducted inquiry into the present condition of all the patients thus operated upon in that institution from 1883 up to May, 1889, has been made in the present year by Leisse (*Archiv für Gynäkologie*, No. 40, 1891, Heft 2). The majority of these patients surviving, were examined with a view to determine local conditions; a few only were unavailable, and replied by letter.

From 1883 to May, 1889, in all, eighty total extirpations per vaginam were conducted. In all these cases at least two years have elapsed since operation; and out of the eighty, forty-five are still living, and in good health. The majority of the deaths have occurred during the later part of the time embraced; this being accounted for by the statement that a greater skill in operating

has allowed the inclusion of cases previously outside the pale of probable successful operation.

Of the thirty-five deaths, eight were due to other diseases *e. g.*, phthisis, etc.; so that the mortality, after a probation of two years, is lowered to 37.5 per cent, due to recurrence. Sixty-two and a-half per cent, therefore, of the cases were successfully operated upon; and this after a two years' test.

The following table of results is given in the *Archiv für Gynäkologie.* S. 265.

2 cases were operated on	7	yrs.	ago;	2	still survive	=	100	p. c.
9 cases had been	6	"	;	6	"	=	66	"
30 " "	5	"	;	18	"	=	60	"
42 " "	4	"	;	25	"	=	59	"
58 " "	3	"	;	34	"	=	58	"
80 " "	2	"	;	45	"	=	56	"

HEROIC GYNÆCOLOGY.

Not long ago it was suggested in many quarters that abdominal section for diseases of the female organs was performed too often. It requires experience and judgment to recognise how far tubes and ovaries are sufficiently diseased to require removal when they have already been exposed by an exploratory incision. Much valuable knowledge has already been gained on this subject, and Polk, of New York, Martin, of Berlin, McCann and Skutsch have successfully performed a conservative and plastic operation on the Fallopian tube. Thus the primitive age of abdominal operations is passing away. Unfortunately, it would appear from a perusal of the European medical press that an era of excess is passing over vaginal surgery. The entire specialist French press was taken up last spring with discussions on a proceeding to which we have hitherto turned little attention. We refer to the total extirpation of the uterus and appendages for chronic inflammatory diseases of the peritonitic type. One operator at least both practiced it extensively and advocated it in the face of violent opposition from the most respected authorities. Another and better-known specialist, in a lecture delivered to pupils, advocates very extreme measures for prolapsus uteri. This affection is, no doubt, a sad inconvenience to stout elderly ladies and workwomen, but it does not endanger life. More than one German gynæcologist, however, has removed the uterus from the vaginal side as a remedy for prolapses. This is surely an extreme measure, but the French teacher referred to above does not consider the removal of a big prolapsed uterus as "extreme." Indeed, he speaks of that operation as *très facile et très bénigne*—minor surgery, as it were. For delivering a woman from the trouble of big uterus by cutting into peritoneum and handling omentum and intestine through a narrow canal hard to keep free from sepsis is, it would appear, a mere preliminary. The patient's comfort is not yet assured, for prolapse of the vagina is very likely to follow. The vagina must, therefore, be sewn up, or narrowed by a plastic operation—then the cure will be complete. The above teaching is based upon some of the principles which the true scientific and practical man of physic studiously deprecates; still more studiously does he avoid teaching them to his pupils.—*British Medical Journal.*

PÆDIATRICS.

PARAFFINE IN DIPHTHERIA.

Mr. A. M. Sydney-Turner, Surgeon to the Gloucester County Infirmary, informs the *Lancet,* in reply to inquiries, that he has treated thirty cases of diphtheria (children and adults) with paraffine, and has had the satisfaction of seeing every one recover. His plan is to ask for the ordinary paraffine used in lamps, and having scraped off the diphtheritic patch, to apply the paraffine every hour to the throat (internally) with a large camel's hair brush. As a rule, the throat gets well in from twenty-four to forty-eight hours, and with improvement in the throat the paraffine is applied less frequently, but he continues to use it for two or three days after the complete disappearance of the patches. He speaks definitely as to the therapeutic effects, but is unable to state what the chemical action of paraffine on the diphtheritic membrane is; probably the hydrocarbons in the liquid exert some powerful influence on the membrane.—*Scientific American.*

COCAINE IN PERTUSSIS.

Dr. A. Bianchi administers the hydrochlorate internally in doses of thirty to eighty centigrammes per day, giving a dose every two or three hours; and in bad cases even as much as one gramme. No evil effects were observed; on the contrary, from the very first there was an improvement. The attacks became less frequent, from thirty or forty in the twenty-four hours to ten or twelve, or even less. The vomiting ceased, and consequently nutrition improved; along with the appetite the gastro-enteric functions were performed with regularity. The cure in some cases was complete in a week, in others from fifteen to twenty days. The cough did not cease, but the spasmodic attacks became less

and less frequent and severe. Sudden cessation of the medicine was followed by a return of the frequency of the attacks, but gradual withdrawal was satisfactory. Ill effects were seen only twice, and passed away suddenly on suspending the administration of the medicine and giving ten drops of laudanum. In the cough of bronchitis or phthisis cocaine appears to be useless or uncertain.—*Lo Sperimentale.*

HYGIENE.

PREDISPOSITION TO TUBERCULOUS INFECTION.

Professor Birch Hirshfield, of Leipzig, comments on the question of predisposition to tuberculous infection, pointing out that the prevailing theory of direct infection by inoculation of the bacillus is rapidly coming to be regarded as the only important factor in the spread of the disease. Predisposition may be classed as "general" and "local," meaning by the first term a greater or less resistance to the development of tubercle; and by the second, the various factors that incline an individual organ or part to become tuberculous. General predisposition may be inherited or acquired, as in the case of diabetes. Local predisposition may depend upon the condition of the local tissues, the opportunities which they afford for the entrance of the tubuculous virus, and the amount of resistance which they set up against its development. Inherited predisposition is strengthened by the fact that, up to the present time, the evidence of direct conveyance of the disease from mother to fœtus in utero has not been well established in the human species, although undoubted instances have been reported as occurring amoung certain animals. Dr. Birch-Hirschfield relates a case in which a fœtus was removed from the uterus of a women aged twenty-three, within a few moments of her death from general tuberculosis, without any damage being done to the placenta. Portions of the liver, spleen and kidney of the fœtus produced tuberculous disease when inoculated into rabbits and guinea-pigs, but only in the capillaries of the liver could any tubercle bacilli be discovered. In the placenta, however, the villous spaces were crowded with bacilli. The very limited evidence of tuberculous material in the fœtus might serve as an explanation of the fact that children of tuberculous parents are often born without any manifestations of tuberculous disease, and yet appear to develop tubercle during the first few years of life. A limited infection by the maternal bacilli, perhaps during the process of birth, might remain latent in one or more organs until other circumstances contribute to their development. It is thus possible that confusion may exist between "latent tubercle" and "tuberculous predisposition." That latent tubercle may remain quiescent, especially in bronchial glands, until awakened by an attack of acute disease, such as measles or whooping cough, is well known. The frequent occurrence of such latent tuberculous foci, without any other evidence of tuberculous disease, goes far to prove that resistance to tubercle is as powerful a factor as predisposition. The congestive influences of valvular disease of the heart and of emphysema upon the connective tissues of the lungs are examples of some of the mechanical causes which constitute resistance.—*Weiner Medizinische Blätter.*

ALCOHOL AND DEATH-RATES.

In a letter published in the *Times*, Dr. C. R. Drysdale has brought together some statistics as to the effects of alcohol on health which are worthy of preservation. He states that in 1890 the actual claims in the temperance section of the United Kingdom Temperance and General Provident Institution of London were 71.6 per ccnt of the expected claims; whereas, in the general section, the actual claims were 100.2 per cent. of the expected. The Sceptre Life Association, between 1884 and 1888, showed that the deaths of the insured in the general section were 79 per cent. of the expected deaths, as compared with 54.4 per cent. in the temperance section. The Rechabites, a total abstinence friendly society, shows at all ages from 20 to 73 a lower annual death-rate than that of the Ancient Order of Foresters. At the age of 20 the death-rate per 1,000 among the Foresters being 7.29, it is 5.59 among the Rechabites; at 30, 8.07 in the former to 5.12; at 40, 12.0 to 6.46; at 50, 18.65 to 11.97; at 60, 33.66 to 25.15 among the Foresters and Rechabites respectively. The Sons of Temperance also had a very low mortality, not exceeding 7.5 per 1.000 per annum of those insured. After the age of 44 the sickness-rate of the Sons of Temperance seems not to exceed one week yearly up to the age of 54, whereas in the non-abstaining Foresters and Odd Fellows it rises gradually from one week yearly up to the age of 44 to six weeks at 54. At all ages the annual death-rate of the Sons of Temperance is much below that of either the Foresters or Odd Fellows. At all ages from 25 to 65 the annual death-rate of the Rechabites was considerably below that of the Foresters, the healthy males of England

and Wales, and the "healthy males" of twenty life insurance companies. Accidents appear to be commoner and more dangerous among non-abstainers than among abstainers. Thus the Lancashire and Yorkshire Accident Insurance Company gives an abatement of 10 per cent. to all total abstainers on their premiums when they have been insured for a year, as do the Accident Insurance Company and the British Empire Mutual Insurance Company.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

BORAX-BORIC ACID.

The somewhat feeble solubility of boric acid in water (1 in 25) has induced Mr. Jaenicke, of Goerlitz, to search for a substance which would increase its solubility without interfering with its uses. He found borax to be the most suitable. Equal parts of borax and boric acid can be made to crystallize together in form of hard crystals, which are soluble in about 6.5 parts of water at the ordinary indoor temperature, in about 3.3 parts at 100° F., and in about 1.3 parts at boiling. If a hot saturated solution is rapidly cooled, it will separate the excess of the salt, not immediately, but after some time only; hence it is possible to use supersaturated solutions in certain cases.—*Therap. Monatsch.*, No. 9, 477.

ACETONURIA IN THE INSANE.

Drs. Boeck and Slosse, who have been engaged in examining the urine of insane patients for acetone, remark that great care must be employed in the collection of the urine; the flasks must be absolutely full and efficiently stoppered, or, better still, the distillation should be commenced immediately. Lieben's iodoform reaction was found to be the most suitable one for indicating the existence of minute quantities of acetone. Gunning's test may also be used, and if these two give negative results, all others are superfluous. The perchloride of iron test is useless for acetone, but is characteristic of diacetic acid. Acetone may exist in the urine under physiological conditions; its importance depends upon the quantity of nitrogen in the food. A small quantity, therefore, in the urine of insane patients is of no importance whatever. The amount did not appear to have any relation to the mental state of the patient—that is to say, to the existence of such conditions as depression, excitement, fear, or delusions. The quantity of acetone increases considerably when the body is in a state of inanition. It is a good plan, according to Drs. Boeck and Slosse, to commence artificial feeding when a patient who will not eat passes urine containing a large proportion of acetone.—*Lancet.*

NEWS AND MISCELLANY.

THE PAN-AMERICAN MEDICAL CONGRESS AT THE UNITED STATES OF COLOMBIA.

Pursuant to nominations by Dr. Pedro M. Ibañez, of Bogota, member of the International Executive Committee for the United States of Colombia the following organization of the Pan-American Medical Congress has been effected in that country:

Vice-President, Dr. Pio Rengifo, New York; *Secretaries of Sections—General Medicine*, Dr. Ignacio Gutierrez Ponce, Paris; *General Surgery*, Dr. Rafael Rocha Castilla, Bogotá; *Military, Medicine, and Surgery*, Dr. Abraham Aparicio, Bogotá; *Obstetrics*, Dr. Joaquin Maldonado, Bogotá; *Gynecology and Abdominal Surgery*, Dr. Jose M. Buendia, Bogotá; *Therapeutics*, Dr. Manuel Plata Azuero, Guadnas; *Anatomy*, Dr. Joan D. Herrara, Bogotá; *Physiology*, Dr. Antonio Bargas Vega, Bogotá; *Pathology*, Dr. Nicolas Osorio, Bogotá; *Diseases of Children*, Dr. Ant. Gomez Calvo, Bogotá; *Ophthalmology*, Dr. Proto Gomez, Bogotá; *Laryngology and Rhinology*, Dr. Luis Fonnegra, Bogotá; *Otology*, Dr. Carlos Guerra, Bogotá: *Dermatology*, Dr. Daniel E. Coronado, Bogotá; *Orthopædics*, Dr. Juan E. Manrigue, Bogotá; *Naval Hygiene and Quarantine*, Gabriel I. Castaneda, Bogotá; *General Hygiene and Demography*, ——; *Mental and Nervous Diseases*, Dr. Pablo Garcia Medina, Bogotá; *Oral and Dental Surgery*, Dr. Guillermo Vargas Paredes, Bogotá; *Medical Pedagogics*, Dr. Jorge Vargas, Bogota; *Medical Jurisprudence*, Dr. Leoncio Barrets, Bogotá; *Auxiliary Committee* (each member being the official representative of the Congress in his respective city), Dr. Nicolas Osorio, Dr. Andrés Posada Arango, Dr. Jorge E. Delgado, Dr. Eugenio de la Hoz, Dr. Domingo Cagiao, Dr. José Manuel Rodrígues, Dr. Paulo Emilio Villar, Dr. Felix M. Hernández, Dr. Rafael Calvo, Dr. N. Ribón, Dr. Milceades Castro, Dr. Cayetano Lombana, Dr. José M. Martinez, Dr. Isaias Saavedra, Dr. Severo Forres, Dr. N. Villa, Dr. Evaristo Garcia, Dr. Miguel Caicedo, Dr. Emilio Villamizar,.

The following medical societies have been elected as auxiliaries of the Congress, viz. Academia Nacional de Medicina, Academia

de Medicina de Medellin, Sociedad de Medicina del Cauca.

The following medical journals have been designated as official organs of the Congress, viz., *Revistá Médica,* Bogotá; *Revistá de Higiene,* Bogotá; *El Agricultor,* Bogotá; *Boletin de Medicina del Cauca,* Cali; *Anales de la Academia de Medicina de Medellin,* Medellin.

The expressed wish of the profession of the United States of Colombia is for a date of meeting during the Columbian Exposition.

CHARLES A. L. REED,
Cincinnati, Jan. 17th. *Secretary General.*

SALICYLAMIDE.

The pharmacology of salicylamide is the subject of a preliminary communication from Dr. W. R. Nesbitt, of Toronto. As the result of a number of experiments, the author expresses the opinion that for therapeutic purposes salicylamide presents advantages over salicylic acid and its salts, in being free from taste, more soluble than salicylic acid, acting more promptly and in smaller doses, having greater analgesic properties, and being pharmacologically safer. Salicylamide $C_6H_4\begin{cases}OH\\CO.NH_2\end{cases}$ was first prepared by Limpricht, by treating gaultheria oil with concentrated solution of ammonia—a method preferred by the author, as avoiding the possibility of introducing foreign toxic compounds, as might be the case when an artificially produced methyl salicylate is used.

When ammonia and gaultheria oil have stood together in the cold for some days, the liquid assumes a deep reddish-brown color, and separation takes place in brown crystals that can be easily purified by recrystallization. From a saturated solution rapidly cooled it separates in an acicular form, otherwise it occurs in thin, long plates or bunches of plates. By treatment with charcoal, Dr. Nesbitt found it easy to obtain perfectly colorless, thin transparent plates, melting at 142° C., soluble in alcohol, ether, chloroform, and about 250 parts of water. Salicylamide is quite tasteless, but produces a gritty sensation between the teeth. It is excreted in the urine partly unaltered, but chiefly as salicyluric acid. It possesses decided germicidal properties, and it was found that both diastatic and peptic changes are retarded by it, but not to the same extent as by salicylic acid.—*Therap. Gazette.*

PRESENCE OF FATTY ACIDS IN SO-CALLED DEFATTED COTTON.

The *Pharmaceutische Centralhalle* states that M. Leick, having treated a number of specimens of cotton wadding, sold as entirely free from grease, to exhaustion with ether and subsequent distillation, the author obtained in every case a solid etheric extract varying from ½ of 1 per cent. to 1.15 per cent. of the weight of the cotton so treated. This extract reddened litmus paper, and proved to be composed almost entirely of fatty acids, with a minute proportion of resinous matters. The author, continuing his investigations, found that these acids were purposely added by the manufacturers in order to give the wadding a whiter appearance and that crepitant feeling which is peculiar to it. The author concludes that inasmuch that as presence of the acids may be an obj ction under certain circumstances, he would recommend the testing of all "defatted" cotton wadding in the following manner: Weigh out 20 gm. of the wadding, exhaust by ether, and evaporate the latter. After desiccation, the residue should not be more than 3 cg.

EXTIRPATION OF CARBUNCLE.

Dr. Riedel has practiced immediate extirpation of carbuncles since 1883, and finds that this procedure is far preferable to the customary treatment by deep incisions. The operation is performed as follows: A circular incision is made through the skin around the infiltrated area, and from this a number of vertical incisions are made to radiate toward the healthy peripheral parts. At least four cutaneous flaps are thus formed, which are separated from the infiltrated tissues, and then the latter are dissected off from the fascia of the subjacent muscles. The hæmorrhage, which is frequently profuse, is controlled by means of compression and tampons. On the evening of the day of operation the temperature has usually become normal. On the following day the swollen cutaneous flaps are approximated; the opening in the centre provides for drainage. The advantages of this treatment are: 1. A dangerous inflammatory focus is replaced within half an hour by a perfectly harmless loss of substance in the skin and subcutaneous tissue. 2. An extension of the local process or general infection are both excluded. 3. The loss of healthy integument at the periphery of the carbuncle is

reduced to a minimum. 4. For this reason healing takes place rapidly and a good cicatrix results.—*Deut. Medicin. Wochenschr.*, No. 27, 1891.

ANTISEPSIS: PUERPERAL MORTALITY IN PARIS HOSPITALS.

Our own correspondent in Paris last week gave interesting particulars confirmatory of the immense benefits conferred on parturient women by the application of antisepsis to obstetrics. We commend the account to the careful attention of our readers. He says, out of 1340 women delivered in Prof. Tarnier's wards during the past academical year only fourteen died, thus giving the very satisfactory mortality of 1 in 95, or 1.04 per cent. Eight years ago the mortality calculated on the same number of cases reached 2.50 per cent.; while, thirty years ago, one parturient out of eleven, or 9 per cent., died. These figures prove conclusively that modern methods of conducting labor are responsible for the saving, in his wards alone, of 100 valuable lives per annum. This is a very gratifying report of progress and advance, and perhaps our correspondent is right in thinking that the virtue of antisepsis can go no further. Puerperal fever is now unknown in the wards of M. Tarnier, whose memory goes back to a time when he witnessed five deaths in one day from puerperal peritonitis; but there is still room, perhaps, for better results, if we may judge from the experience of some of our London lying-in hospitals. In one of these, during the years 1888 and 1889, there was but one death in 1272 successive deliveries.—*Lancet.*

TREATMENT OF UTERINE FIBROIDS BY COMBINED GALVANIZATION AND FARADIZATION.

Dr. Baraduc has devised a new electrical treatment of uterine fibroids, which consists in the joint use of the galvanic and faradic currents, applying both electrodes to the abdominal walls or on the cervix, and the other to the abdomen. The apparatus consists of a galvanic battery capable of furnishing a current of 250 milliamperes, a coarse faradic coil, and two very moist tampons to be pressed very firmly against the wet skin, so as to localize the current which should invade the uterus at one of its two axes. After one, or perhaps more than one *séance*, a positive diminution may be observed in the mass of the tumor, which is manifested by a depression of the form and size of the electrode, at the side of its application. This percutaneous procedure is based not only upon the contractile, circulatory, and resorbent power of the faradic vibrations, but also, and especially upon its disintegrating and oxidizing action. It is especially applicable to inoperable abdominal fibroids that are impenetrable to the uterine sound. The operation consists of three steps: (1) The application and maintenance by strong pressure of the two rheaphores upon the abdominal walls, or of the cutaneous rheaphore if the other is used *per vaginam*. (2) The established current completely utilized, muscular contraction ceases because of the penetration of the current, which the patient no longer feels, its action being wholly spent upon the tumor. (3) Gradual increase of the galvanic current while maintaining the rapidity of the faradic vibrations. Dr. Baraduc reports one case of immense abdominal fibroid which had been refused operation by Pean, but which was relieved of all urgent symptoms by the combined electrical treatment just described, while at the same time it was reduced in volume one-half.—*Journal de Médicine de Paris*, October, 1891.

ICHTHYOL IN GYNÆOLOGIGAL PRACTICE.

Dr. J. Eschen (*Gynäkologiske og Obstetriske Meddeler*, Bd. 8, S. 281) has used ichthyol in gynæcological cases, according to Freund's, of Strassburg, instructions, with, however, not such astonishing results as many clinicians report. He obtained eczema and universal erythema as side-actions. In some cases, as of metritis, parametritis, oöphoritis and peri-oöphoritis, he obtained good results, but, unfortunately, sometimes the remedy did not respond. The disagreeable eructations following its administration by the stomach were neutralized by the addition of cumarin, four centigrammes (three-fourths of a grain) to each pill.

LIST OF MEDICAL JOURNALS.

Dr. Ferdinand King proposes publishing in an early edition of *The Doctor's Weekly* "a complete list of medical, dental, pharmaceutical, veterinary, and scientific journals."

SULFONAL-BAYER.

Sulfonal-Bayer is a "pure hypnotic" because it gives a purely hypnotic action and produces no other effect. It is a "true nerve sedative" because its action continues after the remedy is discontinued. Sulfonal is used in all Insomnias, Insanity, and in all cases in which hypnotics are indicated. It is a *safe remedy*, and it does not give rise to a drug habit. Very reliable and effective, its action is slower than that of the narcotics; hence, care must be taken to give it as directed. It is supplied in ounces; also in tablets and pills.

ARISTOL.

In all Ulcerations, Skin Diseases, Lesions of the Eye, Ear, Nose, Mouth and other cavities; in Dysentary, Gonorrhœa, Ivy-poisoning, Burns, Scalds, Blisters and all external traumatisms, Aristol has shown itself to be a safe and effective remedy. It is also given (hypodermically), in Phthisis. It is used in ointments, powders, crayons, suppositories, oils, sprays, collodions, tampons, bandages, etc. Aristol Gauze is now widely used *in the place of Iodoform Gauze*, so long offensive to physicians. Aristol is supplied in ounces only.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

URTICARIA, PSORIASIS, AND SYCOSIS

By HENRY W. STELWAGON, M. D.,

CLINICAL LECTURER ON DERMATOLOGY, JEFFERSON MEDICAL COLLEGE.

URTICARIA.

Gentlemen: — The first case I have to bring before you this morning represents a disease not at all uncommon. The lesions, which you see are scattered, consist of pinkish-white pea-sized, rounded and flattened elevations, with the peripheral portion of each of a more pronounced tint; here and there they are broader and tend to be linear, appearing as pinkish-white streaks. The eruption is a markedly itchy one, as shown by the existing excoriations and scratch-marks. These several characters of the eruption, coupled with the fact that the individual lesions are fugacious, disappearing in a few hours, and also that similar lesions may be brought out by running the finger briskly over the skin, point unmistakably to urticaria. In almost all cases this disease is an acute one, lasting several hours or days to one or two weeks, rarely longer. In exceptional instances, it is true, the eruption may persist for several months or years, the skin rarely being entirely free from lesions, constituting what is termed chronic urticaria. The lesions themselves are not chronic, as they are usually as evanescent as in the common type of urticaria, but new efflorescences continue to appear and reappear almost indefinitely. The causes of acute urticaria are usually to be found in some disturbance of the digestive tract. Acute indigestion will, in some individuals give rise to an attack. There are those also who cannot eat crabs, clams, lobster or such food without the supervention of acute urticaria; the same may be said of strawberries, and in fact the list could readily be added to. The ingestion of certain drugs is the exciting factor in some cases. The causes of chronic urticaria are not always evident; it is often provoked and kept up by dyspeptic conditions, by disturbances, functional or organic, of the genito-urinary organs, and by a depressed condition of the nervous system.

The diagnosis of urticaria is rarely difficult; it is likely to be confounded with but one disease, and that is erythema multiforme, especially the papular type of the latter disease. The important differences are these: The lesions of urticaria are markedly itchy and are fugacious, the individual efflorescences rarely lasting more than a few hours; they show predilection for covered parts, but with no special localization; the lesions of erythema multiforme are more persistent, usually lasting several days or a week or more, are rarely itchy to an annoying degree, and show special preference for certain regions as the backs of the hands, the forearms, and the lower parts of the legs and the face. The prognosis of urticaria as ordinarily met with is favorable, the attack subsiding, upon removal of the cause, in a few hours or several days. In so-called chronic urticaria the outlook is not, unfortunately, always so hopeful, although most of such cases, if the etiological factors are properly studied and appropriate treatment instituted, will gradually and finally yield.

The treatment of acute urticaria consists in the removal of the cause, usually stomachic or intestinal disturbance, by the administration of saline laxatives and antacids. A laxative antacid deserving of special mention is the ordinary calcined magnesia, a sufficiently large dose being given to produce free action of the bowels. Or an ordinary saline, such as Epsom or Rochelle salt, or Hunyadi water may be prescribed, and an antacid such as sodium salicylate or bicarbonate administered in five grain doses three or four times daily. Emetics are sometimes advised for removing the offending material

from the stomach, but this is only called for in those exceptional cases of urticaria in which the mucous membranes of the throat share in the eruption, the patient's breathing being seriously interfered with. In the present case intestinal sluggishness, as evidenced by constipation, a coated tongue, etc., point toward the treatment to be advised. A mildly laxative dose of magnesia, repeated daily for a few days if the eruption persists, will, in all probability, be all that is needed. One point to be brought out in connection with the present case is the possibility of the eruption being due to medication. The patient has been in the hospital for fifteen days and he has had urticaria for thirteen days, a suspicious coincidence; he is subject to phthisis, and is in the hospital and is under treatment for that disease. The several drugs commonly given to control cough in bronchial or pneumonic conditions are opium, chloral, etc. Moreover, not infrequently the balsamic oils, such as oil of copaiba, or oil of turpentine, are given for their action upon themucous membranes. These several remedies are in certain subjects capable of causing urticaria, and must be, as in this case, eliminated as the acting cause. For chronic urticaria successful treatment depends upon the discovery and proper appreciation of the etiological factor or factors in the individual case, and their correction or removal by appropriate remedies. Generally speaking, exclusive of those cases demanding tonic treatment, the remedies most frequently of service are sodium salicylate, belladonna or its alkaloid atropia, ergot in full doses, and the various mildly laxative alkaline mineral waters.

In all the more marked cases of urticaria external applications for the relief of the itching are to be prescribed. Among the most efficient may be mentioned carbolic acid lotions, one to three drachms to a pint of water, to which a drachm of glycerine and one or two ounces of alcohol may be added; a lotion of thymol, the carbolic acid of the above being replaced by fifteen to sixty grains of thymol and lotions of equal parts of vinegar and water.

PSORIASIS.

The second case, now exhibited to you, is one of marked type and extensive development. You see on this man's forehead the sharply-defined border of inflammatory eruption which extends from the scalp. The border is not straight, but is evidently made up of contiguous rounded patches which have become confluent, giving rise to a wavy line. The same condition is seen behind the ears extending from the scalp, and the same also upon the neck posteriorly; in these two latter regions one or two quarter-dollar sized rounded, inflammatory, scaly, sharply-defined patches remain distinctly separated from the main eruption of the scalp. The face, as often occurs in this disease, is free. The diagnosis may readily be made from a study of the eruption upon these parts without inspecting the general surface. The diseases suggested are eczema, of the squamous type, and psoriasis. Were the eruption of a milder and less inflammatory type, seborrhœa would also have to be considered in the diagnosis. Eczema is to be excluded by the facts that it is rarely so scaly as the eruption before us, it never limits itself by such an abrupt and sharply-defined border, and it does not occur in rounded, sharply-defined patches as here seen back of the ear and on the neck. Moreover, the disease in this case has always been dry; in an eczema of long duration, whatever its prevailing type, there is usually evidence or a clear history, at one time or another, of the characteristic oozing of that disease. On the contrary, all the characters of the eruption before us as already briefly described, show the disease to be psoriasis. Now, as soon as this man's body is uncovered you see that the same characters as seen in the eruption upon the scalp and contiguous parts are presented, and as is always the case, much more clearly and emphatically. Here are a few pinhead—the beginning lesions—numerous pea-, dime-, half-dollar-, dollar-, and palm-sized, sharply-defined, inflammatory scaly patches, in some places becoming confluent and covering large areas. The disease as seen in this patient is unusually extensive, and is much more so than the average case of psoriasis met with. Upon inquiry we find that this man has had the disease for eight years, during which time it has varied considerably, once or twice the skin being almost entirely free. In the milder types of psoriasis the eruption will frequently disappear entirely during the warm months. In the milder type also, there may be some difficulty in distinguishing the eruption from the papulo-squamous syphiloderm, but usually in the syphiloderma several or more purely papular and characteristic lesions may be found, and other symptoms of syphilis may be commonly discovered. In the particular case before you, the eruption could not be confounded with any syphilitic manifestation, the patches are too large, too red, too scaly, and the disease of too long duration; the papulo-squamous syphiloderm is an affair of months, not of years, as psoriasis usually is.

As to the cause of this disease, we know little, the subjects, as a rule, being in a good or fair condition of health. It would seem that in many instances it is an expression of the lithic acid diathesis.

About the treatment, fortunately, we know much more, and in many cases the eruption may be quickly, that is, in the course of several weeks or a few months, removed. Of the few internal remedies useful in the constitutional treatment of this disease, two should be especially referred to. One is arsenic and the other alkalies. In the moderately or markedly inflammatory type represented here, arsenic may or may not do good, and if prescribed, must be used with caution, as the disease when of this type is sometimes made worse by its employment. On the other hand this is just such a case in which you expect the best results from the administration of alkalies. This man is in good health, strong, robust, of good color, and the eruption is of the actively inflammatory type, and in such patients and in this type eruption, alkalies are especially indicated. The favorite, and upon the whole the most available one, is liquor potassa, administered in dosage from five to thirty minims, largely diluted, three times daily. We shall prescribe that remedy in this case, beginning with ten drops and rapidly increasing to twenty. As to the external treatment, the first essential, as in all cases of psoriasis, is to get rid of the scales. This will be most readily accomplished by means of repeated warm alkaline baths. The patient will be directed to take a daily bath. made up of six to eight ounces of the sodium or potassium carbonate to sufficient water to cover himself when in the recumbent position—about thirty to forty gallons. He should remain in this bath for fifteen to thirty minutes, and the warmer the bath the more effective. After a few baths of this kind the probability is that the patches will be entirely free from any scaliness. Should this not be the case, or should this method prove slow, which exceptionally happens, then the scaly areas are to be washed with sapo viridis and hot water, just before he enters the bath. During treatment, and often as an essential part of it, these baths will have to be repeated from time to time. The external remedy to be advised in this case, which is admirably suited for the class of cases this represents, is chrysarobin. It is best applied as a paint. One to two drachms to the ounce of collodion to which five minims of castor oil are added, will be found a convenient formula. Or the paint may be made of chrysarobin and a solution of gutta-percha. The one selected is painted over the patches, the paint immediately drying into a more or less elastic film. At the end of a day or two, from detachment or from cracking of the film, a repainting will be found necessary, and so on, until applications are no longer needed. Usually, at the end of a week or ten days the application must be intermitted, owing to the tendency to dermatic inflammation of the surrounding skin to which it gives rise. At such times a mild ointment may be applied. This remedy is not applicable to hairy parts, and, as it is a strong one, must be used with care and judgment. It is a good rule not to use it about the face or scalp. Tar ointment, in officinal strength or weakened, is another valuable application and one of probably more general use than chrysarobin. It is to be well rubbed into the diseased areas once or twice daily. The use of a dusting powder after tarry applications renders its use much less unpleasant. To the face and scalp either the tarry ointment will be applied or an ointment of ammoniated mercury, forty to sixty grains to the ounce.

SYCOSIS.

The third case is, as you see, one in which the eruption is only on the face, and a fact that will immediately strike you is that the eruption is confined to the beard. It has lasted several years and has never shown any disposition to extend beyond the bearded region. This fact is of great help in aiding you to reach a correct diagnosis, for it immediately brings the probable diagnosis to either non-parasitic sycosis or parasitic sycosis. Examining the eruption more carefully, you will see that it consists of a more or less diffused redness, some slight infiltration, and here and there some discrete papulo-pustules and pustules, each pierced by a hair. There is no perceptible hair loss, and no lumpiness of the parts. Parasitic sycosis–tinea trichophytina barbæ, barber's itch—is readily excluded by the absence of conspicuous hair loss, absence of lumpiness, and the non-involvement of the hairs; these being firmly seated and neither brittle nor broken. On the other hand, you find the symptoms correspond exactly with those of non-parasitic sycosis—sycosis, folliculitis barbæ. This latter is a follicular inflammation of the bearded region, characterized by varying degrees of inflammatory action, with, usually, numerous minute papules and pustules, each pierced by a hair, and with little tendency to positive hair loss. No lumpiness occurs in this disease. If still in doubt between the two diseases in a case of this kind, extract some of the hairs, and ex-

amine with a power of three to five hundred diameters; the fungus is readily found if the disease is parasitic sycosis. The etiology of sycosis is obscure. Like most pustular processes it is probably microbic, but even accepting this, we would yet be ignorant of the necessary underlying or predisposing conditions. Internal treatment is of questionable service. Tonics should be prescribed if the tate of the patient's general health indicates heir use. In some instances calx sulphurata, in one-tenth to one-fourth grain dose several times daily, seems to be of some value. The external treatment is, however, that upon which reliance is to be placed for successful results in this disease. If the parts are actively inflamed, the hair is to be clipped short and mild and soothing applications made for a few days. At the end of this time, and at the very start in the average case met with, shaving is to be advised. This is somewhat painful for the first two or three times, but is of material aid in curing the disease. Personally I should hesitate to treat a case of sycosis unless the patient be willing that the parts be shaved every day, or second day, as circumstances demanded. Instead of shaving epilation may be practised. This is useful, but in my experience is objected to much more frequently as being more painful than is shaving. In all cases those hairs around which there is considerable suppurative inflammation, should be extracted, so as to save the involved follicle from possible destruction. Several remedies for you to remember in connection with the external treatment of this disease, one of which will be prescribed in the case before you, are precipitated sulphur, ichthyol, and Vleminckx's solution. These are exeeding valuable, and if used with judgment, will often lead to a successful result. Precipitated sulphur is prescribed in ointment form, one to two drachms to the ounce. A valuable combination is the following, although it be open to the objection of chemical incompatibility: ℞ Precipitated sulphur, ʒ jss.; balsam of Peru, ʒ ss.; diachylon ointment, ʒ vi. If a good quality of diachylon ointment is not obtainable, cold cream or equal parts of petrolatum and lard may be substituted. This, as all stimulating ointments in the treatment of this disease, is to be well rubbed in, morning and evening. Ichthyol is prescribed in ten to twenty-five per cent. ointments; or it may be prescribed with sulphur with any ordinary ointment base. Vleminckx's solution, the remaining important remedy I desire to mention, is to be applied weakened with five or six parts of water, the affected region being thoroughly dabbed with it for several minutes night and morning. The strength of this application should be gradually increased, stopping just short of irritation. In conjunction with this solution it is necessary to employ a mild ointment, either a mild ichthyol or sulphur ointment, from time to time, to counteract the dryness and scaliness produced. The strong tendency to recurrence exhibited by this disease, will be greatly lessened if shaving is practised for several months or a year or more after the existing symptoms have been removed.

COMMUNICATIONS.

THE INFLUENZA BACILLUS.*

I.—PRELIMINARY COMMUNICATION ON THE EXCITING CAUSES OF INFLUENZA.

By Dr. R. PFEIFFER,
BERLIN, GERMANY.

The following results are based on the accurate examination of 31 cases of influenza, in 6 of which a necropsy was made. A complete report will be published as soon as possible.

1. In all the cases of influenza a bacillus of a definite species was found in the characteristic purulent bronchial secretion. In uncomplicated cases of influenza these tiny bacilli were found in absolutely pure cultures, and mostly in immense quantities. They were very frequently situated in the protoplasm of the pus corpuscles. If the influenza had attacked persons whose bronchial tubes were already otherwise diseased—as, for example, phthisical patients with cavities—other micro-organisms besides the influenza bacilli were found in the expectoration in variable quantity. The bacilli may penetrate from the bronchial tubes into the peribronchitic tissue, and even reach the surface of the pleura, where, in two cases examined *post mortem*, they were found in pure cultures in the purulent exudation.

2. These bacilli were found exclusively in cases of influenza. Very numerous control examinations proved their absence in ordinary bronchial catarrh, pneumonia, and phthisis.

3. The presence of bacilli kept equal pace with the course of the disease; with the cessation of the purulent bronchial secretion the bacilli began to disappear.

**Deutsche Medicinische Wochenschrift and British Medical Journal.*

4. I had already seen and photographed similar bacilli in the same enormous quantities two years ago, during the first epidemic of influenza, in preparations of the sputum of patients suffering from the disease.

5. The influenza bacilli appear as very tiny rodlets, of about the thickness of the bacilli of mouse septicæmia, but only half the length of these. One often sees three or four bacilli strung together in the form of a chain. They stain with some difficulty with the basic aniline dyes. Better preparations are obtained with dilute Ziel's solution and with hot Loeffler's methylene blue. In this way it can be seen almost, as a rule, that the two ends of the bacilli take the stain more intensely, so that forms are produced which can only with great difficulty be distinguished from diplococci or streptococci. In fact I am inclined to believe that some of the earlier observers also saw the bacilli described by me, but that, misled by their peculiar behavior with regard to staining agents, they described them as diplococci or streptococci. They cannot be stained by Gram's method. In hanging drops they are immobile.

6. These bacilli can be obtained in pure cultures. On 1½ per cent. sugar agar the colonies appear as extremely small droplets, clear as water, often only recognizable with a lens. Their continued culture on this nutrient medium is attended with difficulties, and up to the present I have not succeeded in carrying it beyond the second generation.

7. Numerous inoculation experiments were made on apes, rabbits, guinea-pigs, rats, pigeons and mice. Only in apes and rabbits could positive results be obtained. The other species of animals showed themselves refractory to influenza.

8. In view of these results I consider myself justified in pronouncing the bacilli just described to be the exciting causes of influenza.

9. It is very probable that infection is produced by sputum charged with the germs of the disease; and the disinfection of the sputa of patients suffering from influenza is therefore urgently required as a prophylactic measure.

Addendum—Dr. Kitasato has succeeded in cultivating the influenza bacilli to the fifth generation on glycerine agar.

Sneezing favors the expulsion of the child in a case of labor, hence the use of tobacco snuff or pepper, or other substances that will bring on the paroxysm by irritating the scheneiderian membrane, will hasten a tardy delivery.

II—ON THE INFLUENZA BACILLUS AND THE MODE OF CULTIVATING IT.

By DR. S. KITASATO.

It is, perhaps, remarkable that in the case of a disease which, in the last few years, has attacked hundreds of thousands of persons, the specific exciting causes have, in spite of extremely numerous investigations, only lately been discovered. The cause, in my opinion, lies in the extreme difficulty of cultivating the tiny bacillus here before you; and, without pure cultures, the bacteriologist cannot, of course, come before the public with a new specific micro-organism.

The difficulty of obtaining cultures of specific bacteria present in the sputum depends chiefly on the great contamination of them with micro-organisms from the mouth, etc. The latter, in consequence of their more luxuriant and abundant growth, can, on our artificial nutrient media, completely overgrow and hide the particular parasites sought for. This occurs all the more easily the longer the specific parasitic micro-organism in question takes to form colonies, as, in fact, happened in the case of the tubercle bacillus.

With the view of avoiding the obstacles standing in the way of a successful cultivation, Privy Councillor Koch has devised a method, which has not yet been published, which enabled him many years ago, and myself again quite recently, to obtain pure cultures of tubercle bacilli directly from the sputum, and which has also been followed by me in the pure cultures of tubercle bacilli here before you. The method to which I have just referred will be published in full detail in an early number of the *Deutsche medicinische Wochenschrift.*

With regard to the characteristics of the pure cultures of influenza bacilli here before you, I may emphasize the following points: On a sloping surface of set glycerine agar the individual colonies present themselves as extremely small points like droplets of water, recognizable during the first twenty-four hours only with the aid of a lens, so that microscopically a test tube containing them can scarcely be distinguished from a sterile one. The individual colonies are, as has been said, so unusually small that they may easily be overlooked, and it may thus have happened that previous investigators have overlooked them.

If a culture obtained from such a colony is placed on a new nutrient agar medium, numerous small colonies arise on the moist agar surface, as may be seen in this tube. A

particularly remarkable point about them is that the colonies always remain separate from each other, and do not, as all other species of bacteria known to me do, join together and form a continuous row. This feature is so characteristic that the influenza bacilli can be thereby, with certainty, distinguished from other bacteria.

The possibility of continued cultivation is now demonstrated, and the tubes here before you already form the tenth generation in pure cultures. On gelatine they do not grow, as they do not generally multiply at a lower temperature than 28° C., which is the temperature at which gelatine solidifies. In *bouillon* they grow scantily. In the first twenty-four hours single white particles are seen swiming in the *bouillon*, the intervening fluid being perfectly clear. Later, they sink to the bottom and there form a white, woolly mass, filling the end of the test tube, whilst the supernatant *bouillon* remains entirely clear—a proof that we have to deal with an immobile bacillus. In conclusion, I may remark that I have accurately studied with the microscope, and by culture, for a long time back the sputa of tuberculosis in respect to all the micro-organisms occurring therein besides the tubercle bacillus, and also the sputa of pneumonia, bronchitis, etc.; but the present bacillus, so extraordinarily characteristic in its cultures, and so easy to be recognized, has not come within my experience except in influenza patients.

III.—ON A MICRO-ORGANISM IN THE BLOOD OF INFLUENZA PATIENTS

By Dr. P. CANON,
ASSISTANT-PHYSICIAN, BERLIN.

During the last few weeks I have, under the direction of Dr. Guttmann, examined the blood of twenty influenza patients in stained preparations, and in almost all cases I have found in the blood one and the same micro-organism. The examination of the blood was made in the following way: A drop of blood obtained by pricking the finger was received on a perfectly clean cover-glass; this cover-glass was placed upon another one, and the two then drawn apart. The preparations, after they had been thoroughly dried, were placed in absolute alcohol, in which they were left for at least five minutes. They were then taken out and placed in the following staining solution (Czenzynke's solution): ℞ Concentrated watery solution of methylene blue, 40 grammes; ½ per cent. eosin solution (dissolved in 70 per cent. alcohol), 20 grammes; distilled water, 40 grammes. The cover-glasses immersed in this staining solution were placed in an incubator at a temperature of 37° C., and left there from three to six hours, when they were washed with water, dried, and embedded in Canada balsam. In the preparations of blood made in this manner where the red blood corpuscle were red, and the white ones blue, I found the above-mentioned micro-organism. It is found stained blue, sometimes in large quantities, but mostly sparingly, and only to be identified after a long search (about 4 to 20 in the preparation). Sometimes it appears as a small diplococcus, sometimes, especially when it is more deeply stained, as a short bacillus. In six cases I have found it also in numerous larger and smaller heaps of from 5 to 50 individual microbes with a very characteristic appearance. In these six cases the blood was drawn during a fall of temperature or shortly afterwards; in three of these no further rise of temperature occurred. From three to six days later I failed again to find the micro-organism in the blood in these three last cases. Sometimes I have been able to make the diagnosis of influenza when clinically it was not certain, by means of preparations of the blood alone. I have also found the bacteria in the blood, and, indeed, in considerable quantities in cases where there was no appreciable local lesion, and especially no cough or expectoration. Whilst making the preparations I have generally at the same time made streak inoculations of the blood on agar, glycerine agar, sugar agar, and *bouillon*. In six cases the *bouillon* was injected into mice, partly at once, partly on the following day after it had been in the incubator. These inoculations and experiments on animals always yielded a negative result. As on the basis of my researches, I am of opinion that this micro-organism occurs in the blood of all persons suffering from influenza (at least, in that of those who have fever), and as it is not found in the blood of other persons, and as it is a micro-organism hitherto unknown, I believe that it stands in direct relation to influenza.

Privy Councilor Koch had the goodness to examine some of my preparation—for which I tender him my best thanks—and pointed out that the micro-organism visible in them was identical with the bacterium found by Staff-Surgeon Dr. Pfeiffer, which has been described in the preceding paper, which is published at the same time as mine. I began these researches about the middle of December; I have, however, still a large

number of preparations to stain and to examine. I propose to publish the results of the further research in a later communication. I have to thank Dr. Guttmann and Professor Dr. Sonnenburg, Director of the Surgical Section of the hospital, for kindly placing patients at my disposal.

IV.—SOME REMARKS ON THE INFLUENZA BACILLUS *

By E. KLEIN, M.D., F.R.S.,

LECTURER ON GENERAL ANATOMY, ETC., ST. BARTHOLOMEW'S HOSPITAL.

The account published in the *British Medical Journal* of January 16th, 1892, of the observations of Pfeiffer and Kitasato on the constant and copious occurrence, in the bronchial secretion in cases of influenza, of a species of minute bacilli, well characterized morphologically and culturally, as also the observations of Canon on their occurrence in the blood of influenza cases induce me to give an account of some observations which I have made during the end of December, 1889, and the beginning of January, 1891, that is, during the early presence of the epidemic in London. By the kindness of Dr. Stephen Mackenzie I was enabled to see and examine cases of influenza in the acute stages at Dr. Barnado's home, which I think were amongst the first cases which occurred in London.

Examination of the Blood.—The blood was examined in cover-glass specimens dried in a thin film, stained and mounted, and in cultivation on gelatine and on ordinary nutrient agar. The cases were those of boys between 10 and 15 years of age; all were in the febrile stage, ranging from a few hours to twenty-four hours since the first symptoms appeared. In one out of these six cases there were present in the cover-glass specimens—stained in rubin first, then in methyl blue anilin water—comparatively few minute bacilli; they occurred singly, a few as dumbbells, and only rarely as small groups. As regards thickness, length, and polar staining, they compare completely with those described by Pfeiffer and Canon, but some of the bacilli were quite as long as those of the mouse septicæmia with which Pfeiffer compares them. In the remaining five cases no bacilli of any kind could be discovered in the specimens. All the tubes inoculated with the blood of these six cases remained sterile.

Examination of Bronchial Sputum.—This was examined in three early cases, which had passed a few days previously through the acute febrile stage and were without fever when examined; they had bronchitis with fairly copious greyish purulent sputum.

Case I.—E. F., a lad about 16 years of age, had a febrile attack for two day, and was kept in the infirmary for several days afterwards. Sputum, after well rinsing out the mouth, was brought up and used for cover glass specimens and afterwards for cultivations. The cover-glass specimens revealed a condition such as is described by Pfeiffer of some of his uncomplicated cases, namely, minute thin bacilli in larger and smaller clumps, and in some places almost like a pure cultivation. The bacilli are about the thickness of the bacilli of mouse septicæmia, half their length, and in well stained specimens most of them show the characteristic polar staining pointed out by Pfeiffer; but I find amongst the group of bacilli a good many that are quite as long as the bacilli of mouse septicæmia. From this sputum cultivations were made in the following manner: A particle of the sputum was placed in a few cubic centimetres of sterile salt solution contained in a sterile test tube, well shaken, and from this dilution gelatine tubes, broth tubes and agar tubes were inoculated. The broth and agar tubes were incubated at 37° C. Some of the broth tubes became turbid after twenty-four hours, others remained perfectly limpid and already after twenty-four to forty-eight hours showed at the bottom of the fluid glassy fluffy masses which increased in amount on the following days, the supernatant broth remaining quite clear. When shaken the fluffy masses broke up easily into filamentous translucent flakes. In the agar tubes there also appeared growth; in some tubes a few translucent colonies looking like flat droplets of water, other colonies opaque and white. In the gelatine tubes there appeared only liquefying white colonies.

Subcultures were then made of the broth tubes which contained only the fluffy glassy growth at the buttom of the fluid. The subcultures were made on gelatine, on agar, and in broth. The gelatine tubes kept at 20° C. remained sterile; the agar tubes incubated at 37° C. developed colonies of exactly the same kind, which in all respects compare with those described by Kitasato: circular small translucent droplet, with no tendency to become confluent. In the broth tubes incubated at 37° C., the growth was characteristic, namely, while the broth remained perfectly limpid there developed at the bottom of the fluid the characteristic glassy fluffy masses; these were noticed already after twenty-four hours, but became more conspicuous after forty-eight to seventy-two hours.

One fact which on further subcultures became very conspicuous was the rapid death of the cultures, both on agar and in broth, but more so in the former than in the latter. The agar cultures already after a week failed to yield new subcultures; the broth tubes after from ten days to a fortnight lost their vitality.

Cover-glass specimens made of the fluffy masses from the broth cultures and of similar fluffy masses in the condensation water of the agar cultures showed the growth to be entirely made up of strings and filaments; each filament is composed of short thin rods, some stained uniformly, the great majority, however, showing a granule at each end;

* From last issue of *Brit. Med. Jour.*

for this reason the filaments look exactly like streptococcus chains composed of dumbbell cocci, but the presence amongst them of uniform bacillary elements without polar staining proves the organism a leptothrix of minute bacilli. The specimens are very remarkably uniform and striking, being entirely made up of these filaments, interlacing and in bundles. Cover-glass specimens made of the colonies grown on agar show also filaments, but a good many groups of the minute bacilli; the groups more completely resembles in appearance the groups that were seen in the sputum. The organisms of all the cultures stained well in rubin (2 per cent. watery solution), in methyl blue anilin water, or in gentian violet anilin water. I have large number of these specimens, and on examining a them with only a moderately high power, the filaments could not be distinguished from streptococci made up of diplococci, but under an oil immersion their bacillary character is easily asertained. each diplococcus being really a short bacillus with a stained granule at each end. In all specimens, those of broth culture, of agar condensation water, and of colonies on agar, there are present in the filaments numerous elements which, owing to their great thickness and irregular shape, compare with involution forms; in broth cultures they are numerously present already after forty-eight hours.

From this it is seen that what is here stated of the bacillus, in the sputum in broth and agar cultures, completely coincides with and confirms what is described by Pfeiffer and Kitasato. One appearance which is not mentioned by Kitasato or Pfeiffer in their preliminary account, and which seems to be a very striking appearance, is that the growth in broth is entirely made up of filaments.

Case II.—The second case in which the sputum was examined was J. M., a lad about 14; had bronchitis after the febrile stage had passed. When I saw him he had no fever, and was about the seventh or eighth day after the first onset of the disease. The cover-glass specimens of this sputum revealed also changes of the same minute bacilli; there was no dificulty in finding the bacilli in the substance of the pus corpuscles, but there never were more than a few bacilli in each one corpuscle. Most of the bacilli showed the polar-stained granules. Also from this sputum, after dilution, successful broth cultures were obtained the same glassy fluffy masses at the bottom of the broth, which was otherwise limpid.

Case III.—The third case was that of a young man, A. A., aged about 20. Had bronchitis for several days after the febrile attack, but was getting better. Not much sputum could be got from him; cover-glass specimens showed some of the minute bacilli, either single or in small groups, but neither were they present in large masses, nor could they be found in the pus cells. Cultivations in broth and on agar failed to produce the characteristic growth.

The broth cultures obtained from cases E. F. and J. M. were used for inoculation of a number of mice and guinea-pigs, but no result, local or general, was produced.

In every case of gonorrhœa warn your patient of the danger of conveying the disease to the eyes by the fingers, and of the fearful results of gonorrhœal ophthalmia.

V.—CONCERNING INFLUENZA.*

ITS HISTORY.

The whole of the English-speaking people, nay, the world, has within the last few days been most feelingly persuaded of the present power of influenza. A prince of great though quiet promise has fallen in our midst, and a great churchman has been taken from his long but not yet finished work. These events have excited a profound interest, and, with the private and personal losses which are felt on every hand, have sufficed to concentrate an unprecedented attention on the subject of epidemic influenza. Panic on such occasions as this among the general public and their teachers, frequently alternates with apathy. But if the panic, which has undoubtedly arisen, can be turned to a useful and healthy purpose, the great sufferings the nation has undergone will not be in vain. Of the history of influenza, enough and more than enough is known; it is one of the recorded diseases of antiquity, and we have sufficient evidence to show that in all probability the epidemic under which we now lie is the same as those of the past ages. We can only here instance that some Hebrew antiquarian authorities hold that in the Talmud are to be found records of a very similar, if not identical, pestilence; that the researches of Dr. Clemow have thrown much curious light on similar visitations affecting Europe in the Middle Ages, and that the classic work of the late Dr. Theophilus Thompson connects our present with these past records in an unbroken chain of evidence.

In the bright light of modern research it may perhaps appear merely historical to note that among the first clear upholders of the germ theory of disease were our countrymen Dr. Richard Dunning and Sir Henry Holland, the latter of whom, in a remarkable and almost prophetic paper, dimly foresaw that organic cloud which now occupies the whole attention of some of the most enterprising of our profession. Sir Thomas Watson, in his *Principles*, adopted and disseminated this view of Holland's and took as a working hypothesis, a sheer hypothesis, in his own words, that "like yeast in beer we may conceive that diseases produced by animalcules (microbes) may thus infect the fluids of the body and become contagious in the fullest sense of that term."

THE THEORY OF CONTAGION.

The theory that influenza is mainly if not entirely spread by contagion is no new one,

---

*Editorial in last issue of Brit. Med. Journ.

bu this idea has needed to be born again. The careful evidence collected by Gray and Haygarth in the past, and the Local Government Board Report of Dr. Parsons in the immediate present, show, to quote Dr. Buchanan's pregnant words in his preface to this report, that "Influenza is an eminently infectious complaint, communicable in the ordinary personal relations of individuals one with another." Influenza having been thus authoritatively asserted to be infectious, how can this conclusion be practically applied in the direction of prevention? Various prophylactics have been recommended; these may or may not be of use, but the only reliable course to stay the spread of the disease is that, where practicable, persons affected with influenza should be isolated, and that healthy persons should, as far as possible, avoid being exposed to chances of infection. Anyone who has influenza is in duty bound to do all that in him lies by avoiding places of public resort, and by refusing to mix freely among his friends to hinder his becoming a disseminating centre of sickness and of death. Much is to be hoped from a general recognition of this truth by the profession and the public, more, indeed, than from the too strenuous application of any powers already possessed by public medical authorities. This part of the question deserves, therefore, a more close study, towards which the paper by Dr. Richard Sisley, which we publish in another column, is an interesting contribution.

SANITARY ADMINISTRATION.

Sanitary science during the last half-century has won so many triumphs over infectious diseases, has learnt so well how to diminish the severity and extent of epidemics which it does not yet know how to suppress altogether, that the public are beginning to demand that it should seriously attempt to grapple with the disease which we in this country have elected to know by the name of influenza. The Society of Medical Officers of Health, at their meeting on January 19th, passed a resolution on the subject which is worthy of a little examination. The resolution set forth that in the opinion of that Society "influenza is a dangerous infectious disease." To some this resolution may seem a belated expression of opinion. The view was very clearly expressed by Dr. Buchanan in his preface to Dr. Parson's Report. The resolution, however, is not, it may be presumed, intended to be a mere pious opinion, but to be a basis for future preventive measures. What is to be the nature of the action to be taken?

The question is not easy to answer. Are we to understand that the epidemics of influenza are to be met in the future by the application of the ordinary methods of sanitary adminstration? The two great principles of modern hygiene have been the removal of unfavorable conditions in the environment—bad drainage, insufficient ventilation, over-crowding, and so forth—which tend to make communities sasceptible to the inroads of disease, and the isolation of persons actually suffering from infectious maladies. As to the first of these procedures we may claim to have seen some result from what has already been accomplished in this country, since the effect of the recent and present epidemics of influenza on the death-rate has been less in this country, on the whole, than in any other. As to the other methods of sanitary administration, it is doubtful how far they are applicable to influenza.

Dr. Buchanan, in the preface from which we have already quoted, after observing that the disease had been shown to belong to a "class of diseases over which we exercise a measure of control," goes on to admit that "from what we have thus far seen of the specialities of influenza, we cannot feel particularly confident of our ability, under the existing conditions of society, to successfully defend ourselves against a further outbreak." Notification has been suggested as though it were a kind of panacea; but what use could be made of the information thus obtained? As is well shown by Dr. Sisley, long before it could be acted upon the mischief would have been done. The disease is certainly infectious in a very early stage, and the symptoms are so largely subjective that it may well be doubted whether notification would result in bringing to light the earliest cases. If this be so, it is certain that it would be useless at a later stage of an epidemic in any given locality. When two-thirds of the households, and perhaps not far short of a fourth of the adult population, are suffering from the disease, is isolation of the sick anything more than a dream? It is quite a different thing with such diseases as scarlet fever or even measles. The objective symptoms are obvious, and one attack is an almost perfect protection from another. It is not unreasonable to punish a man who exposes himself, or a person under his charge, in a public conveyance while suffering from scarlet fever; would public opinion sanction similar punishment of a man who felt a little ill, or had the symptoms of a more than usually severe cold, and went home in a public conveyance?

The truth is that before we can attempt to stay the pandemics of influenza we must know a great deal more about it. As Dr. Buchanan has said, "For better means of repressing influenza our expectation must be in an understanding of the natural history of the disease." We do not know whence it comes, we do not know for certain how it spreads—whether mainly by air, water, or even by fomites; we do not know whether the complications which render the disease so much more formidable than it would otherwise be are due to the primary infective agent, or whether they are produced by a secondary infection, as was generally supposed during the epidemic of 1889-90; we do not know whether the disease which frequently attacks horses and other domestic animals at about the some time as mankind is the same disease or not; and, lastly, we do not even know the measure of protection which one attack affords against a second.

It is reasonable to hope that the researches now being carried on in Berlin may result in placing valuable practical methods of dealing with the disease in our hands. We were enabled to publish last week translations of the important papers by Pfeiffer, Kitasato, and Canon, which appeared in the *Deutsche medicinische Wochenschrift* of the same week. They deserve careful study. The proof that the bacillus described is the *vera causa* of influenza is not absolute, but there is very strong presumption that it is. Much may be learnt from the study of the life-history of this microbe, but even then much will remain to be learnt as to the "natural history" of the disease. The Government of this country may very fairly be asked to contribute its share to the inter-national study of the pandemic. Dr. Parson's Report is a valuable document, and any future inquiry would have the advantage of starting where he left off; but a great many questions remain to be answered, some of which we have indicated above.

SYMPTOMS AND TREATMENT.

A rational systematic mode of treatment is of course impossible, so long as the etiology remains obscure, and hence we have at present to rely upon the main symptoms for indications. The sudden onset of febrility, the spinal tenderness so commonly met with, the pains in the limbs, the photophobia, the pronounced lassitude and anorexia, and lastly the tendency of the temperature to sink below the normal when convalescence sets in—all these facts point to the severe impression made by the infective virus upon the cerebro-spinal nerve-centres. Accordingly, it is of great importance that the patient should early have rest and warmth in bed, that the diet should be of a supporting character, and that he should remain in bed till all danger of complications has passed away. These simple points appear mere truisms, but they constitute the best preventive against the insidious development of catarrhal pneumonia, the great danger to be guarded against. It is not advisable to attempt to cut short the malady by active diaphoretic measures; abundant experience has shown the futility of such treatment. Rest, warmth, and nourishment constitute the tripod of treatment. Domestic isolation is strongly to be recommended for the sake of others.

In respect to drug quinine has been found useful by some, who have even gone so far as to declare it a prophylactic. Small doses of opium constitute a powerful support to the central nervous system, but this drug should be used with caution if any bronchitis is present, and abandoned altogether if signs of capillary bronchitis supervene. A combination of salicylic acid and antipyrin has been lately put forward under the name of salipyrin, and it is claimed for this mixture that it does not depress the system as does either of the constituents taken alone. It certainly deserves a trial, but its effects should be carefully watched. Salicylate of quinine is probably a still better preparation, but the salicylic acid employed should be naturally, not synthetically, obtained. The natural product is far less depressing than its artificial substitute. Good suceess is claimed for an antiseptic (carbolic acid) treatment but it remains for a larger experience to determine with what correctness.

It will generally be found that alcoholic stimulants are well tolerated in influenza, but they should not be given to such an extent as to disorder the digestion. During convalescence the patient should still keep quiet and warm for some time, and not be in a hurry to resume the ordinary avocation. The various psychoses which have been recorded after influenza plainly show that this disease is a powerful depressant of the central nervous system, and it is often several weeks before the patient again enjoys the usual vigor of mind and body. The insidious onset of pulmonary mischief afterwards is also best guarded against by keeping the patient in a uniform temperature. Iron, acids and quinine will be found useful in hastening convalescenec.

Strychnine is used as an antidote for snake bite in Australia.

THE PART THE SHOULDERS PLAY IN PRODUCING LACERATION OF THE PERINEUM, WITH SUGGESTIONS FOR ITS PREVENTION.

By W. D. HAGGARD, M. D,,
NASHVILLE, TENN.

The most important point connected with the second stage of labor, and the most delicate task the accoucheur has to fulfill is to properly care for and protect the perineum during the exit of the child's head and shoulders.

The wide divergence of opinion prevailing among the ablest and best authors on obstetrics with reference to this subject, betrays such a want of agreement on many questions connected with the mechanism of head and shoulder delivery, that I feel some hesitancy in presenting my views on a subject which has been so often and so ably handled. Perineal support in some form or other was for a long time recommended by most obstetrical authorities; but such support was for the most part confined to the period occupied in the passage of the head, ignoring any claim the perineum might have to support during the more perilous passage of the shoulders.

Smellie advocated artificial dilatation of the outlet; Roederer, pressing the perineum in the direction of the sacrum; Puzo, stretching and lubricating the parts; Hamilton, of Edinburgh, agreed with Puzo in the use of lubricants, but further advised that the perineum be cautiously pushed back over the face and chin, when the head is being born. All of these procedures, as we shall see, differ widely from the more modern practice.

Dr. Ramsbotham says: "As soon as the head has come to press upon the external parts it becomes our duty to take our seat by the bedside, and never move from our position till the child has passed. This we do to prevent laceration." "Place your elbows," he continues, "against the bedstead, regarding it as a fixed point, and allow the perineum to be forced against your hand."

This dogmatic teaching, coming from one of the most distinguished obstetricians of his day, probably exercised a greater influence in favor of perineal support on the professional mind than did all his predecessors.

Many years ago, in a case of forceps delivery, he looked with great care after the delivery of the head, to see if any laceration had occurred, and found only a slight tear. After the passage of the shoulders he found the tear extended down to the verge of the sphincter ani. This case made an indelible impression on his mind, and from that time until the present he has never failed to make an ocular inspection, both after the passage of the head, and again after the passage of the trunk and shoulders. He is sorry to say that he can now recall vividly a number of cases in which he has found a similar result, especially in forceps delivery, for some abnormality which would have resulted in rupture without their use. For a long time he consoled himself with the thought that the unfortunate cases occurred in women in which there was a disproportion in the size of the head and shoulders, or between the vulvar outlet and the child. A larger experience, and a closer observation of the mechanism of head and shoulder deliveries, has convinced him that a large number of lacerations that occur are avoidable, with the precautions which experience has taught him are required.

Lacerations in a certain per cent. of cases, and under certain conditions are wholly unavoidable, do what we may to prevent such a result. A knowledge of this fact has probably kept back for ages, advances and improvements, especially in the way of determining the proper application of the much-needed support. That the mode of supporting the perineum for ages was faulty in the extreme, he proposes to show. He thinks a little reflection will make it plain that the earlier writers on obstetric medicine, as well as some of the present day, placed entirely too much stress on perineal support. It is equally plain that they attached too much importance to the head as a factor in effecting lacerations.

If we recall for a moment the mechanism of the delivery of the head, and compare it with the more speedy delivery of the shoulders, and reflect upon the requirements of nature, it is obvious, that so far as dilatation is concerned, that the functional activity of the physiological requirements by which dilatation is effected is much better provided during the slow stretching effected by the head than the rapid distention induced by the passage of the shoulders.

Goodell is perhaps more pronounced in his opposition to perineal support, and gives more cogent and plausible reasons therefor than anyone who has written on the subject. He considers the word "support" a misnomer as applied to the perineum, and that the head instead of the perineum needs support. He thinks that if the support ever does any good, it is by retarding the head through the interposed perineum, and that the good thus

obtained is overbalanced by the evil. He suggests that if the hand be held continually against the perineum, it becomes unyielding and incapable of equable dilatation, and the strain is thrown on the fourchette.

His instruction for supporting the head in its exit through the vulvar outlet is admirable. He holds that when the pains are abnormally strong, the passage of the head should be retarded by supporting it with two fingers in the rectum, while with the thumb of the same hand he makes the needful restraining pressure upon the head.

If with the passage of the head the danger were ended, his dicta would be perfect, but unfortunately it is not. Leishman says, "It is not by the passage of the head that the most serious lacerations are effected; they are often commenced by this, but it is the passage of the shoulder which extends the rupture."

It is singular that Goodell in his able and comprehensive description of the management of head deliveries should have overlooked the fact that the shoulders should be an object of even more solicitude on account of the greater peril to the perineal structures.

Lusk says, "In the majority of cases, the shoulders are expelled spontaneously, still it is a good plan to expedite the descent by pressure made with the left hand at the fundus of the uterus." The above sentence is so much at variance with the sound teaching of its author, as well as most other modern authorities, that I am at a loss to see how he could recommend pressure over the fundus to expedite labor, when it is so desirable that the shoulders should be allowed all the time possible to effect dilatation in the perineum now firmly contracted around the child's neck, "Unless there are symptoms of threatened asphyxia in the child," said Leishman, "or circumstances which demand immediate delivery, we would not in any way interfere in the birth of the trunk, which will be naturally effected after a short pause, generally counted by seconds."

Thus we find Leishman squarely in opposition to Lusk in his advice to expedite the descent of the trunk by pressure made with the left hand at the fundus of the uterus. It is true he says in the next sentence, "care must be taken lest the lower shoulder convert a slight tear in the perineum into an extensive laceration"—a contingency all the more likely to occur if the delivery be expedited by pressure as he directs. Then follows this most judicous counsel: "The right hand should therefore be applied to the perineum in such away as to lift the shoulders upward and at the same time furnish a bridge over which it can glide in its movement forward." Whereas Playfair, Leishman, and Lusk all recognize the serious danger encountered in the delivery of the shoulders, but none of them except Lusk make provision for tiding the perineum over the last and most serious danger of laceration during the passage of the shoulders.

During the passage of the cephalic ovoid the pressure is equally distributed over the entire surface of the vulvar outlet, so that every fiber and tissue entering into the complex anatomical structure of the perineal body is placed under contribution. And thus the highest functional activity of the organ is attained.

As soon as the head rotates on its longitudinal axis and the occupant emerges under the symphysis pubis, the chin sweeps over the floor of the pelvis with the head in extreme extension. As soon as it is delivered, flexions on its transverse axis takes place, the chin falls forward, concealing the perineum and anus, if the woman be in a dorsal position from view, and this may account for the supposition that the laceration discovered after the birth of the child occurred during the passage of the head. The perineum now rapidly and forcibly contracts around the child's neek. During the short interval of repose that follows the delivery of the head the uterus gathers itself for a final effort, which speedily culminates in a strong propulsive pain, often of sufficient strength, supplemented by the auxiliary forces, to hurl the child forcibly into the world. At this time rotation of the shoulders and restitution of the head takes place almost simultaneously. In the haste to complete delivery, every means is resorted to by some, such as compression of the fundus, and even pulling upon the neck, and hence I urge that it becomes us to keep well in mind the mechanism of labor, and restrain the delivery of the shoulders until they have adapted themselves to the long diameter of the outlet. The posterior shoulder, unsupported as it must be with the woman occupying the dorsal position, literally plows its way through the perineal body, laying it wide asunder in its passage. That perineal lacerations occur more frequently if the woman be delivered in the dorsal position than upon the side, has been abundantly proven by the statistics of Schroeder and others.

Lusk says, "During the third stage the patient's posture should be left in general to her own volition. The physician should accustom himself to conduct labor with equal

facility, no matter whether the woman lies upon her side or upon her back. The left lateral position, affected by English accoucheurs, is very convenient at the time of delivery, especially when there is occasion to support the perineum, and where, owing to the flatness of the nates, the vulva is scarcely raised, in the dorsal posture, above the level of the bedding."

Ramsbotham says, "The most convenient as well as easy posture which the patient can take, and which seems the best adapted for facilitating the descent of the head through the pelvic outlet, is the one usually chosen in this country, the left side, with the shoulder inclined forwards so that the spine may be somewhat curved, the thighs flexed upon the pelvis, and the legs bent upon the thighs. In this position, as has been before shown, the axis of the pelvic entrance is brought as nearly as can be accomplished into a line with the axis of the trunk; the muscles passing over the pelvic brim, particularly the psoas, are more perfectly relaxed than any other." Hence it follows that the obstetrician who has due regard for the integrity of the perineum, should insist upon the patient occupying this position. Rapid delivery is such a frequent source of laceration, that it should never be encouraged except in the face of an emergency requiring speedy delivery, either in the interest of the mother, or child, or both. In forceps cases all possible safe-guards should be thrown around the vulvar outlet to protect it from injury by desisting from tractile efforts during the acme of pain, and as soon as the head begins to emerge from under the symphysis the forceps should be removed and the labor left to the natural resources. The head should now be supported as hereinafter directed, and the delivery of the shoulders should be effected under such restraining influences as will insure the protection of the perineum, if possible.

He has shown that the shoulders are responsible for the major part of perineal tears, frequently by extending a slight rupture into a deep laceration, often through the sphincter ani, extending up the gut to a greater or less degree. Why is this so? A little reflection will make it apparent that there is a good and sufficient reason found in the fact that the oval shape of the head gradually effects an equable, well directed pressure upon each and every tissue forming the pelvic outlet, while each recurring pain brings into requisition some new force, until the entire structure is laid under contribution in bringing into play the highest and fullest physiological function of the perineal body. When dilatation to its fullest extent is obtained, it generally admits the passage of the head without rupturing the perineum.

Whereas, in the delivery of the trunk and shoulders the perineum is placed at the greatest possible mechanical disadvantage by the increased power which the uterus gains by its diminution in size, effected by contractility after the birth of the head; besides the perineum, immediately after the passage of the head, rapidly and forcibly contracts around the child's neck. As soon as the head is born a short pause ensues. The uterus, now reinforced by additional contractile power, gathers itself for renewed effort, which is now sufficiently powerful to overcome all resistance. Therefore, if the perineum cannot or will not stretch to make room for the body to pass, it must tear, and tear it will, unless the rapid advance of the shoulders be retarded by judicious support until the perineum relaxes, as he believes it will generally do, especially if aided by the relaxing influences of chloroform, which is both speedy and effectual in its effects.

This lesson teaches us the necessity of placing the woman on her left side, so as to give the accoucheur a better opportunity to retard the passage of the shoulders by affording the needful support to the presenting part. It is clear that the dorsal position affords no facility whatever for restraining the passage of the body when uterine contractions are sufficiently strong to overcome the resisting powers of the perineal body.

With this array of facts before us, he does not think the choice of positions—at least during the second stage of labor—is any longer a debatable question.

Then why may we not all meet on one common plane and agree upon the left side position as the ideal one to be observed in obstetric practice? If we, as practitioners of the obstetric art could agree upon this, and forever eschew the fallacious idea that the perineum needed support, and leave it to take care of itself, as nature intended it should do, we might then devote our time and skill to the support and restraining influence of judicious and timely pressure applied to the presenting part of the child until sufficient dilatation of the vulvar outlet was obtained to allow the passage of the shoulders and trunk with as little disturbance of the perineal structure as did the passage of the head.

Slowly, but surely, year by year, will these great truths, so plainly foreshadowed by Goodell, Lusk, Leishman and Playfair, be

impressed upon the minds of the medical profession. It is true that every foot of scientific advance in obstetric medicine has been contested by fallacious arguments and traditions that have for centuries been handed down from one to another. It is true that error cannot be eradicated in a day. The process must be one of gradual evolution, followed by verification.

The suggestions which I wish to make from a study of this paper are:

1. The patient should occupy the left lateral decubitis, at least during the second stage of labor.

2. Overcome rigidity of the vulvar outlet by the judicious use of chloroform.

3. The presenting part of the child should be supported, and not the perineum, during the passage of the head and shoulders.

4. Support the head by pressing it well up under the symphysis pubis, by placing the right thumb in the rectum and fingers of right hand expanded over the occiput.

5. To retard the exit of the shoulders, pressure should be applied to the trunk and shoulders by placing index and middle fingers of the left hand in the rectum, with the thumb in the vagina, to restrain its exit.

6. With the right hand restraining and supporting the head and neck by pressing well over the symphysis pubis the head and neck.

REGULATION OF HYPNOTISM IN BELGIUM.

The first land which has undertaken the legal regulation of the practice of hypnotism is Belgium. A few days ago the Legislature adopted a law which, in all probability, will serve as a model for the legislative action of other countries. It declares that any one who exhibits publicly a person hypnotized by himself or others will be punished by imprisonment ranging from two weeks to six months, and be fined from $5 to $200; that any one not in possession of a physician's diploma who hypnotizes a person under twenty years of age, or not in the full possession of his faculties, will be punished by imprisonment and fine, whether the subject be exhibited or not; and that any one who allows a hypnotized person to sign a document or other paper, whatever its nature, with the object of fraud, will be punished by imprisonment. The same penalty threatens a person who attempts to use a document signed by one while hypnotized. The people of Belgium have welcomed the adoption of the new law.

ACUTE RHEUMATISM.*

By JAMES FRAUNFELTER, M. D.,
CANTON, OHIO.

The name "Acute Rheumatism" was first applied to this disease in 1642, but at what date the disease first make its appearance is not known. It is not my purpose, in this paper, to enter into a discussion of all the etiological factors, or the theories of blood changes occurring in acute rheumatism; neither do I hope to offer anything especially new in the study of this disease, but, I propose to outline some of the main points of interest in reference, more particularly, to the etiology, nature and treatment of acute rheumatism, as it presents itself to me, after twenty years' experience with the disease, which, to me has been the most perplexing, on account of its uncertain course, at times baffling my efforts at every point.

Much has been written concerning its character, and volumes have been devoted to its various systems of treatment, which, from time to time, have held the favor of medical writers, yet we feel that the subject is still not exhausted. Whilst we must admit that much is unsatisfactory, and new facts are continually being discovered, there yet remains a field for the active investigator to discover more for the advancement of the welfare of suffering mankind.

With this end in view I hope to be able, in this paper, to suggest some conclusions on the cause, nature and treatment of this disease which a somewhat extensive study on this subject, together with my personal experience, have developed.

Rheumatism is a constitutional disease resulting from the accumulation of excretory products in the system, and may be defined as being a specific inflammation which attacks the structures in and around the joints, more especially the larger joints, the inflammation changing from one to another, and is rarely attended with suppuration. In addition to the joint-affection, the fibro-serous structures of the heart are attacked with the inflammatory process, and is generally attended with high fever and nervous conditions, with intense pains in and around the joints.

Rheumatism is not likely to be confounded with any other disease, except pyæmia and gonorrhœal rheumatism; the former always being associated with some wound or lesion, is attended with more marked chills and the

*Read before the Union meeting of the Distric Medical Societies of Northern Ohio, Nov. 7, 1891.

perspiration is not acid. The latter disease is always associated with gonorrhœa, with a marked tendency to attack the knee joint.

As to the etiology of the disease, exposure, cold and dampness, are usually considered the principal factors in the causation of acute rheumatism. Severe muscular exertion, attended by overheating the body and followed by chilling the surface, is a frequent cause. But neither will produce rheumatism unless there is a predisposition to the disease either from hereditary or acquired taint, the former of which is said to be present in about 34 per cent. of all cases. A residence in a cold, damp climate for a long time acts as an exciting cause. Age has a strong predisposing influence, as children under 15 years of age and adults over 45 are not liable to be attacked with the disease, as statistics show that patients are more susceptible to acute rheumatism, between the ages of 15 and 30, males being more frequently attacked than females, probably due to their occupation being more exposed and more frequently engaged in severe muscular exercise. Season and climate are, no doubt, predisposing causes, it being more prevalent in a moist, cold climate.

Occupations which require great muscular effort in a warm atmosphere predispose to it, such as washer-woman, bakers, moulders and laborers generally.

The above are the principal causes which have a tendency to predispose to or excite an attack of acute rheumatism. When we come to speak of the nature of rheumatism, we must regard it as being a constitutional disease, with local inflammations, the fever not being a result of the local inflammation, but the first element in the disease, the inflammatory process being of a specific character and is the result of some poisonous material circulating in the blood, which has a strong tendency to attack the structures in and around the joints and the heart; in other words, those structures subject to severe movement and strain.

Another plausible reason for attacking the joints in preference to other parts of the body is that the special poison of rheumatism, whatever this may be, finds its principal obstruction, while circulating through the tense fibrous tissue of the joints and thus by pressure on the nerves of those parts produces the pain and disturbance characteristic of the disease.

Thus far everything appears plain and satisfactory, but we follow the investigation a little farther, and ask ourselves the question, "What is the nature of this poisonous material?" Then it is we stop and wonder why it is that, in this day and age of progression, especially in the medical profession, that we must admit that we cannot answer the question entirely satisfactorily to ourselves.

I will, however, give some of the views on this subject as given by some of our best medical writers.

In looking over our latest authors on this subject, we find there are several theories advocated, the generally accepted one being the "lactic acid theory," by Prout. Then we have the "miasm" or "malarial" idea by Maclagan, and the "germ" and "nervous" theories, and the "uric acid" theory, by Haig. Some of the arguments in favor of the lactic acid theory are as follows:

1st. Acute rheumatism is always accompanied by an excess of lactic acid in the system, and the disease never occurs without such excess, and such excess is found only in connection with it. 2d. The injection of lactic acid into the system of lower animals is followed by inflammatory changes, similar to those which occur in acute rheumatism. 3d. The administration of lactic acid to man has been followed by symptoms indistinguishable from those of acute rheumatism. The lactic acid theory of Prout, is again modified; the latest being founded upon the modern physiological teaching, that is, during muscular exercise sarco-lactic acid and acid phosphate of potassium are formed and carbon dioxide set free in the muscular tissue, and that cold acting on the surface, under such circumstances, may check the elimination of those substances and cause their accumulation in the system. This is to me the most plausible theory and explains, probably, more clearly than any other, why the muscles and their associated organs, the joints and tendons, should suffer first and chiefly; because the morbid influences are exerted upon them, when exhausted by functional activity. This would also partly account for the excess of acid elimination during the course of the disease,

The "miasmatic" theory is the one advocated by Dr. Meclagan, who assumes that acute rheumatism is caused by the entrance into the system, from without, of some miasm closely allied to but quite distinct from malaria. His arguments in favor of his theory are quite plausible and extensive, the nature of which, he admits, we have no precise knowledge of. To substantiate his theory, however, he compares the different types of malaria fever with acute rheumatism, showing that both diseases are more prevalent in low, damp localities, but that the conditions under which rheumatism was most likely to arise,

were a cold damp climate rather than a warm damp climate. Impressed with this fact and believing in the miasmatic origin of the disease, he states, in the following language, taken from his own writing: "It seems to me that a remedy for this disease was most hopefully to be looked for among those plants and trees whose favorite habitat presented conditions analogous to those under which the rheumatic miasm seemed most to prevail, and upon reflection it seemed that the plants whose haunts best corresponded to this description were those belonging to the natural order Salicacea, the various forms of willow, among this order I determined to search for a medicine for rheumatism," hence our present most effectual remedy for the treatment of this affliction, of which I will speak later.

He concludes from the above that the poison enters the system from without, and its nature was that of a miasm.

The germ theory, like the miasmatic, refers to rheumatism as being the result of a poison or germ, not generated within the system, but introduced from without; this germ, whatever kind it may be, is supposed to enter the blood, through the dilated orifices of the sweat glands, which first set up an endocarditis, then the capillary emboli thus formed produce the articular inflammation; which theory, to me, is pretty far fetched.

The nerve theory is the one advocated by J. K. Mitchell, afterwards by Hutchinson, Gull, Weir Mitchell, and Charcot. According to this theory, the exciting causes, cold and dampness, produce an impression on the surface of the body, which is conducted to the vaso-motor and trophic centres by the afferent nerves, the joints and other structures becoming affected through these systems. After thoroughly investigating this theory, we find so many lame features in it that, to me, it is not very plausible.

The "uric acid" theory by Haig is to me the latest on the subject. He argues that because acu te rheumatism is cured by the use of salicylate of sodium, which also, at the same time, produces an enormous excretion of uric acid, therefore, uric acid is the cause of rheumatism. Then again, there is no doubt whatever, but that salicylate of sodium relieves the pain, and brings down the temperature. It also causes, at the same time, a relatively large excretion of uric acid. Besides the salicylates, the only drugs that have obtained any great repute in the treatment of this disease are the alkalies, and these, again, promote a free excretion of uric acid. He shows pretty conclusively, to his own mind, at least, that a large amount of the uric acid excreted does not come from the kidney direct, but from a store in other parts of the body, as the joints or viscera.

The conclusion is that if this uric acid came from the joints its presence there was quite sufficient to account for all the pain and fever of an attack of acute rheumatism.

After making a pretty thorough investigation of this subject, I find the above to be the different theories advanced for our future consideration, and, after carefully studying these different ideas, and comparing them, we arrive at the following conclusion in reference to the nature of rheumatism: That the inflammation is the result of some special poison, generated within the system, circulating in the blood, and from our present knowledge, lactic acid appears to be the most prominent and plausible.

It has been my experience to be able, almost invariably, to trace every case of acute rheumatism as being due to prolonged muscular exercise and cooling off too suddenly, or working in a cold, damp place; and in accordance with our late physiological teaching, during such exercise sarco-lactic acid is generated in the muscles; the surface becoming chilled, this acid is not eliminated as it should or would be under other circumstances, causing it to accumulate, thus producing its specific effect in and around the joints, hereditary taint being an important factor in all cases.

When we come to speak of the treatment of acute rheumatism we should expect to find it about as unreliable and unsatisfactory, as the nature of the disease is uncertain. If the acid theory of the disease is correct, then we should be able to treat the disease on scientific principles, by prescribing alkalies; again, should the disease be due to a miasm, then the successful method of treatment would naturally suggest itself, in the remedies—quinine and the different preparations of salicin; but we find from actual experience, that neither are successful, in all cases, and that, after all, our treatment of acute rheumatism, is not scientific but empirical.

When speaking of the etiology of this disease I neglected to mention that, disturbed nutrition and errors in diet acted as important factors in the development of acute rheumatism, and should be borne in mind, when we come to speak of the treatment, which naturally divides itself into preventive and curative. Persons who are necessarily exposed to the exciting causes of rheumatism should be encourged to wear woolen next to the skin so as to prevent their bodies from chilling as

much as possible, and when there is a predisposition and a susceptibility to the disease, they should be advised to remove to a warm dry climate, with sandy soil, in a location not over-crowded with trees, exposed to sunlight and with a free circulation of air. Morning baths with tepid salt water, followed with thorough friction of the whole body, acts as a strong preventive. When heated or over-tired from severe exertion, standing about in a cool atmosphere should be avoided. I feel confident that if the above preventive measures were adhered to closely, there would be very few cases of rheumatism for us to treat. The hygienic treatment of a patient suffering from rheumatism is also very important and should demand our strict attention. When possible to do so, the patient should be placed in a large well-ventilated room, the temperature being kept constantly and regularly at from 68° to 70°; flannel or wool should be worn next to the skin, but the bed clothing should not be so heavy as to increase the perspiration. The whole body should be rubbed off frequently with a dry towel, under the clothing, to remove the excessive perspiration. Placing the patient between blankets, is, I think, a mistake, as it increases, to a marked degree, the already natural tendency to excessive perspiration, thus making the patient more susceptible to relapse. When we come to speak of the diet of rheumatic patients there appears to be a difference of opinion, some claiming that an exclusive starchy and saccharine diet will predispose to bring on attacks of acute rheumatism, and that those persons who adhere strictly to the above diet are more susceptible to the disease, and it should therefore be avoided in the early stages.

It is, however, pretty well agreed by all medical writers that a low unstimulating diet should be observed until all fever and articular inflammation have subsided, the tongue clean and the heart complication, if any, declined.

In the early stages of the disease it is not difficult as a rule, to restrict the patient to a suitable diet, as the difficulty usually is to get them to take enough nourishment, but during convalescence, and when the appetite begins to return, then it is difficult to make a patient believe that a good supply of butcher's meat will retard his progress towards recovery. But as a matter of fact, those of us who have had much experience with rheumatism know that a return to solid food, and more especially the giving of meat too soon, is most likely to be followed by a relapse, because in acute rheumatism the system is loaded with waste products, the result of imperfect assimilation and the digestive functions are seriously impaired. So long, therefore, as the symptoms are acute, small quantities of milk, with some alkaline water, such as soda or lime water, should form the main part of the diet, besides these a little beef-tea, chicken tea, or mutton broth may be added. As the temperature falls and the acute symptoms subside, vegetable soups, bread and other starchy foods may be gradually added to the list; gruels, malted-foods, arrow-root, rice, the yolk of an egg beaten up with milk, and a small quantity of brandy. As convalescence progresses, fish, oysters, and chicken may be allowed once daily. The above line of diet should be adhered to strictly until all symptoms of rheumatism have entirely disappeared.

As a rule ales, wines, and the stronger alcoholic liquids are objectionable, except where the action of the heart is feeble, or in the latter stage of the disease.

In selecting medical remedies for the treatment of acute rheumatism we should use such medicines as our experience has taught us will the most rapidly reduce the pyrexia, allay the pain, and, at the same time, most surely prevent heart complications. In my experience we have the best remedies to this end in salicylate of sodium and strophanthus, the latter being given as a heart tonic. I have selected salicylate of sodium because in it we have combined the alkaline and salicin treatment which has been the most effectual in my cases, and I believe I am safe in saying that the failures with this remedy in many cases may be attributed to not giving large enough doses. In the beginning I commence with gr. xx. doses, repeating every hour until there is decided evidence of its physiological action, and its remedial effects, the indications of which are deafness, the relief of pain and the decline in the temperature of the body, then the doses should be diminished; but this should not be done too quickly as the symptoms are apt to return. Let me state farther, that the success of this treatment depends largely on the continuation of the remedy. Some time after convalescence seems to have been established, in cases where the stomach does not tolerate the remedy I add a little lemon juice, or a mild bitter tonic, and when the stomach obstinately refuses to assimilate it, I substitute salicylic acid or salicin; the latter is most likely to be assimilated and with better effect, only that its action is slower.

If heart symptoms should arise, the salicylate must be stopped at once, and the alka-

line treatment substituted. A choice as to which alkaline remedy should be used is a matter of some importance. I think bicarbonate of sodium is the least depressing, and I often combine with it the salicylate in gr. xx. doses, or I administer it as recommended by Dr. Fuller in ʒiss doses in connection with acetate of potassium in ʒss doses, rendered effervescing at the time of administering it, by adding lemon juice or ʒss of citric acid, in about ʒiii of water which makes a rather pleasant as well as cooling drink. This I repeat every 3 or 4 hours, diminishing the dose as soon as the urine becomes alkaline; continuing this treatment until convalescence is established, in doses sufficient to keep the urine in an alkaline condition. When a cathartic is needed during the progress of the disease, I use Rochelle salts.

I neglected to mention that in the commencement of my treatment in nearly all cases, I begin by giving my favorite prescription—one tablet, containing calomel gr. ¼; pulv. ipecac gr. ½ and sodium bicarbonate gr. ii. every hour until free catharsis is produced; this followed with a light dose of Rochelle salts or a seidlitz powder. In some cases I get good results from the use of ʒi doses of effervescing bicarbonate of potassium, repeated every three hours. Salol acts well in some cases, but I have no confidence in antikammia. Acetanilid, phenacetine and antipyrine should never be administered in this disease. Opium is admissible in all cases where pain is a prominent symptom; given in sufficiently large doses to produce the desired effect. Quinine can be used to advantage in large doses, during the acute stage, especially in malarial districts, and in tonic doses, during the whole time of convalescence. In endemic cases, tincture of iron in large and repeated doses will be attended with good results. Numerous other remedies might be mentioned, but the above is about the line of treatment I have adopted in my practice, and I must say it has been highly gratifying, as I have had but one case of heart complication in all my experience.

Before closing this paper I cannot refrain from giving my experience with the local application of cold in the treatment of this disease, which has not been very extensive, but entirely satisfactory to myself, and very grateful to my patients.

Up to eighteen months ago I used various kinds of liniments, hot applications, wrapping the joints in cotton batting, etc., and, I think, not without some benefit, but since I have used cold applications to the joints I could wish for nothing better, as the almost immediate relief it affords the patient is something wonderful, but you will find that its application requires considerable courage, however, on the part of the physician to use it in the face of the criticism it brings forth from all the old women in the neighborhood, as it is entirely out of the line of the usual way of treating this disease, but I assure you that you will not be disappointed in its use if thoroughly applied, which may best be done by wringing heavy towels out of cold, or even ice, water and wrapping the joints; this may be covered with flannel and changed as often as necessary to keep the part cool. It is important that it should be continuously applied, until all the symptoms of the disease have disappeared. I do not wish to be understood that I claim any originality in the use of cold in the treatment of acute rheumatism, as Drs. Senator, Esmarch, and Stromeyer used it years ago, but I was induced to use it because I have seen its good effects in combating inflammations in other parts of the body, and could see no reason why it should not act in the same way in inflammation of the joints as a result of rheumatic poison.

I would be pleased to have the experience of other physicians on this subject.

(I)—SARCOMA OF THE KIDNEY; (II)—MULTIPLE ABSCESSES OF THE LIVER.*

By J. B. HERRICK, M. D.,
CHICAGO, ILL.

About a year ago a gentleman in apparently good health, aged 65, came under the care of Dr. Charles Warrington Earle for the sudden appearance of blood in the urine. He was put to bed by the doctor, and seemingly recovered after three or four days, the blood completely disappearing.

There was at this time no temperature, no pain, merely the appearance of blood in the urine. At the end of about a week after the apparent recovery, he was up and around, and a week later, that is two weeks from the first appearance of hæmaturia, Dr. Earle was again called to see him because of a recurrence of the previous trouble. There was a larger amount of blood than there had been at first, and the patient complained of some pain in the left lumbar region. He was again

---

*Read before Chicago Pathological Society, Oct. 1891.

put to bed, placed upon ergot and tannic acid; but the hæmaturia still continued, Catheterization was necessary because of the clotting of the blood in the bladder. This catheterization, somewhat to our astonishment, had to be frequently performed; at first, every six or eight hours; later, every two or three hours, and finally even every hour. Towards the last, catheterization was performed by an intelligent medical student. Symptoms of cystitis appeared some time be the patient's death; vesical tenesmus, the appearance of mucus in the urine, together with tenderness and pain in the region of the bladder, and a slight temperature, 99° F. to 102° F. All these symptoms gave evidence of cystitis, and possibly of a slight form of sepsis from the cystitis. The patient gradually became weaker and weaker, and, after an illness of about ten weeks, died. The autopsy findings that were of interest were the following:

The right kidney showed merely the changes of chronic interstitial nephritis or contracted kidney. This kidney, which I hold in my hand, you see is diminished in size; the capsule is adherent in places, the cut surface shows the diminished cortex, with characteristic cysts scattered here and there throughout the kidney. One of these cysts is still unopened. This finding is, perhaps, of no interest, except from this fact, that had operative procedures been instituted in this case, and the left kidney, the one containing the sarcoma, been removed, it is probable that death would have ensued, for this contracted kidney could not do the work of two perfect organs. The left kidney was much enlarged; there was a subcapsular and also a perinephritic hæmorrhage. The upper portion of the kidney was occupied by the new growth. Several microscopists have taken sections from this specimen, so that there is little left of the new growth, yet enough remains to show by the difference in color, feel, and contour, the outlines of the tumor. This on microscopical examination—the examination being made by Dr. Hektoen—was proven to be a sarcoma.*

A third finding of interest, and especially from the light that was thrown on the history of the case by Dr. Earle, was the condition of the gall-bladder, though this has nothing at all to do, so far as can be judged, with the late history of the case. The gall-bladder was small, shrunken or atrophied, contained no bile, had no outlet, the cystic duct being represented by a strip of fibrous tissue. The walls of the gall-bladder were tough and leathery to the feel, and appeared to the naked eye to contain a large amount of fibrous tissue. The gall-bladder contained about thirty gall-stones of varying sizes and shapes, as can be seen in this specimen. There had evidently been a previous cholecystitis where adhesive inflammation had taken place in the cystic duct, resulting in its perfect occlusion and consequent atrophy of the gall-bladder. The moment we found this condition, Dr. Earle said that about ten years before, the patient consulted him for what he regarded as a stomach trouble. It had baffled the skill of several physicians, and the patient made weekly pilgrimages from the South Side to Dr. Earle to receive the treatment that he had instituted. There was quite severe, vague, indefinite pain in the region of the stomach, which gradually disappeared. The disappearance of the pain of course was due to the abatement of the inflammation, the closure of the duct, and the gradual atrophy of the gall-bladder.

A fourth finding, which we came near overlooking, is this: I had almost forgotten to make an incision into the urinary bladder. Drs. Earle and Hoadley had left the room, and there was no one there but the medical student, the son of the dead man, and myself. I cut into the bladder, and the medical student with difficulty suppressed an exclamation of surprise as I lifted this—a broken half of a catheter—into view. And now the question arose, Who introduced this catheter? Dr. Earle knows that he did not; I was absolutely certain that I had not done it, and the medical student said he was innocent. There were then but two persons left who could have done it, the dead man and his daughter. The daughter remarked to us at one time that she thought it was not necessary for a doctor to come over in the night to introduce the catheter, that she could do it and thus save the extra expense if we would allow her to do so. She, perhaps, passed some old catheter, which broke off, and never reported the circumstance to us. This accounted, possibly, for the cystitis from which the patient suffered; also for the tenesmus of which he complained, and for the frequency with which we had to catheterize. The son who stood right there never had the slightest suspicion of anything unusual in the post-mortem findings of the case.

The interest in this case is enhanced by the fact that no other sarcomatous foci were found in chest or abdomen, the sarcoma being apparently primary, a condition of rarity. The cranium was not opened.

*Sections examined by Drs. A. E. Hoadley and G. H. Weaver were pronounced sarcomatous.

MULTIPLE ABSCESSES OF THE LIVER.

This patient came under my care in the Presbyterian Hospital about two months ago. The patient was a married woman of 23 years of age. The brief history showed that she had enjoyed excellent health up to one year prior to her entrance into the hospital, barring one exception, at the age of 12 she suffered from what seemed to be a simple attack of ordinary jaundice. Twelve months before entering the hospital she was taken with a pain in the right hypochondriac region, and was obliged to call in a physician. He suspected the passage of gall-stones, and directed the examination of the stools. No stones were detected. Again, at three different times she was compelled to call in a physician for a recurrence of these severe attacks of pain in the right hypochondriac region. Morphia was required in every instance, the pain lasting from a few hours to one or two days. Jaundice never followed any of these attacks. One week before coming from Wisconsin to enter the hospital, she went to bed one night in perfect health and was suddenly seized with severe pain at one o'clock in the morning. It was thought to be a recurrence of the old attacks of pain in the right side. Morphia was required in this instance, but the pain did not leave as it had previously done. It continued for two or three days, then jaundice began to appear. This alarmed the patient, especially as a slight temperature began to develop. The friends hurried her off to Chicago that she might seek aid there. Upon admission to the hospital, a diagnosis of gall stones with impaction was made, and the question of surgical interference at once came up. After two days' delay, until the patient's friends had arrived from Wisconsin, it was decided not to operate. The case was seen by Drs. Stehman, Graham and Senn, and it was deemed inadvisable to operate because of the low condition of the patient, and the wide diffusion of the inflammation, apparently septic, in so many organs. Tenderness over the upper abdomen with tympany indicated a quite extensive peritonitis. The physical signs, rapid breathing, etc., gave evidence of consolidation of the lower lobe of the right lung, and the anterior portion of the lower lobe of the left. Moreover an endocardial murmur at the mitral valve had developed, and the temperature ranged from 102° F. to 104° F. It seemed certain death on the table if we resorted to an operation. The patient lived much longer than any one expected. For over two weeks her temperature was of an irregular character, often higher in the morning than in the evening. There were sweats but no marked chills. Death occurred about two weeks after admission to the hospital.

The post mortem was made the same afternoon, and the findings in the case showed in the common duct, a solitary smooth, oval gall-stone about the size of a small pigeon's egg. This was situated so as to nearly close the outlet of the duct into the duodenum. This gall-stone lay directly opposite an abnormal opening in the duodenum, which was not large enough to admit of the passage of the gall-stone.

Adhesions had taken place between the duodenum and the common duct; by pressure, atrophy, or ulcerative process there had been formed this new communication between the duct and the intestine. It is probably that had life continued the opening would have grown large enough so that the gall-stone would have dropped into the duodenum, and in this way appeared in the stools. Not only were there adhesions between the duodenum and the common duct, but the peritonitis had resulted in adhesions between the stomach, diaphragm, liver, omentum, and intestinal coils in the upper half of the abdomen. Through this new opening, which existed between the common duct and the duodenum, it is probable infection took place —certainly infection had taken place in some way, for there existed a suppurative cholecystitis, a suppurative cholangitis, multiple abscesses of the liver. The liver on section seemed to be riddled with small abscesses of various sizes. Two, the largest, were the size of a walnut. These were filled with bile-stained pus. In the lower lobe of the right lung there was found consolidation, the appearances of pneumonia in stage of resolution, as also in the lower lobe of the left lung in its anterior and internal portions. These points of consolidation were exactly opposite the adhesions between the lung and the diaphragm, and the diaphragm and the liver. Changes characteristic of recent vegetative endocarditis were found on the mitral and aortic valves.

This case is of interest from an etiological standpoint. An abscess of the liver is rarely primary, save in those cases originating in traumatism. A punctured wound may give entrance to the infective agents; a severe contusion, or a punctured wound from a fractured rib may furnish a point of least resistance where localization of the pus microbes will excite suppuration.

Secondary abscesses may originate in suppurative disease in a neighboring organ.

Purulent pleuritis, or pericarditis; the perforation of a gastric or duodenal ulcer, where adhesion between the stomach or duodenum and the liver had existed, may be the starting point of an hepatic abscess. Metastatic abscesses in the liver often occur, the primary focus being distant. The commonest cause is suppuration in the abdominal organs, whose veins go to make up the portal vein. A dysenteric ulcer, with suppuration, may cause thrombo-phlebitis in one of the radicals of the portal vein. A fragment of the thrombus is detached. When this, being septic, lodges in the liver, it excites suppuration, and hepatic abscesses is the result. This is notably the case in the so-called tropical abscesses, In our temperate climates, however, gall-stones furnish the commonest cause of abscesses, at least of multiple abscesses. Constant irritation of the walls of the gall-bladder and of the ducts, and close proximity to the septic intestinal tract, with which there is direct communication by the avenue of the common duct, and at times, as in this case, by a patent new opening formed by ulceration, give the conditions favorable for suppurative inflammation of the gall bladder, and of the gall ducts. And if the inflammation extends into the intra-hepatic bile ducts, then the parenchyma is almost sure to become the seat of a suppurative inflammation.

I regret that I was unable to bring away from the case any specimens excepting the solitary gall-stone, which is an ordinary-looking one, and a small piece of the liver for microscopic section. The brother stood by and positively refused to allow anything more than that to be taken.

Dr. Charles Warrington Earle: The history of the case, as narrated by Dr. Herrick, together with the exhibition of the specimen, is, to me, exceedingly interesting, because I have followed the case for six or eight years. The patient was 65 or 70 years of age, and lived on Fulton street when I first saw him. At that time he was a well-nourished man, which was still true when he took his bed in his last illness. There has never been a symptom in his entire history that pointed to a malignant disease. He certainly had no cachexia; on the contrary, he was rather ruddy, and his nutrition good, for a man of his age. He enjoyed life remarkably well, and, with the exception of occasionally an attack of pain in the vicinity of his stomach, or what afterward proved to be his gall bladder, had little cause to consult a physician. I do not now remember the complaint from which he was suffering when I first saw him; but for the pain in his stomach, a prescription consisting of muriatic acid, a little pepsin, and pancreatine gave great comfort, and this combination was given many times. I find, upon looking in one of my case-books, that at one time in his history I prescribed cimicifuga and salicylate of soda. It has occurred to me that it is just possible he may have had symptoms of lumbago, although I cannot now remember. If he ever had even a backache, or anything which pointed to malignant disease, I fail to remember it, and also neglected to make any record of it. He was extremely well nourished at the commencement of what proved to be his last sickness, and only took to his bed after repeated hæmorrhages from the urinary tract, and its consequent exhaustion. There was no supposition, even at this time, that there was malignant disease. I believe malignant disease of the kidneys was excluded, largely on account of his good nutrition and lack of cachexia. His principal symptoms were profuse hæmorrhage from the urinary tract, gradual prostration, failure of his strength, terrible vesical tenesmus, and finally more or less collapse and death.

I think we were all surprised when we found sarcoma in the kidney, and more especially were we surprised when we found a catheter in his bladder. As Dr. Herrick has said, he did not introduce it, and I am sure I did not.

LAPAROTOMY UNDER LOCAL ANÆSTHESIA.

Schleich (*Berliner klin. Wochenschrift*, No. 35, 1891), reports three cases in which he performed laparotomy, after inducing local anæsthesia with ether and cocaine. The patient first inhaled only sufficient chloroform to render her partially unconscious. The abdomen was then sprayed with ether until the skin was rendered insensitive. Between forty and fifty superficial and deep injections of a weak solution of cocaine (three-fourths of one per cent.) were then made along the line of the proposed incision, no more than a grain of the alkaloid being used. In order to increase the action of the drug the extremities were encircled with Esmarch's bandages. In the operations described (two ovariotomies and a gastrostomy) the patients were entirely conscious throughout the operation, and stated that the pain was slight, even when peritoneal adhesions were separated. They had no unpleasant symptoms, and made a good recovery. The method is recommended in cases in which ether and chloroform are contra-indicated.—*Amer. Jour. Med. Sci.*

SELECTED FORMULÆ.

TONSILLITIS, RAPID CURE.

℞ Tinct. verat vir. (*Norwood*).....30 drops.
Morp. sulph.....½ grain.
Aq. dest.....9 drams.
M. Sig. Teaspoonful every hour for two hours, and then every two hours as n eded.

—*Med. Rec.*

SCROFULA.

Iodine and iodoform give better results than the alkaline iodides. To young children tincture of iodine may be given, one drop daily in a little thin porridge made of farina and milk. Besnier prefers the use of iodoform, which may be given continuously for a long time. He prescribes it after the following formula:

℞ Iodoformi .....gr. iss.
Mellis.....℥ iv.
M. Sig. One or two teaspoonfuls to be taken.

—*Le Bulletin Médical.*

FALLING OUT OF THE HAIR.

The following is recommended (*O Galenos*, Etos 1, Arithmos 9) in falling out of the hair:

℞ Quiniæ sulphat..... ℥ j.
s lve in
Acid sulphuric., q. s.
adde
Aquæ communis.....fl. ℥ viij.
Aquæ melissæ.....fl ℥ j.
Boraci venetic..... ʒ ij.
Apply to the scalp two or three times a day.

PHOSPHORUS IN RICKETS.

Nettenheimer, according to *Les Nouveaux Remedes*, proposes a new formula to replace that of Kassowitz, who is well known as an expert in such matters, and whose formula is as follows:

℞ Phosphori.....gr 3-20.
Olei amygdal.....℥ xxv.
M. Sig. A teaspoonful to be taken once daily.

Nettenheimer recommends the following as superior:

℞ Phosphori.....gr. 3-20.
Ol. amygdal. dulc.....5 vijss.
Pulv. sacchari alb.,
Pulv. gum arab.....ää ℥ ivs .
Aquæ dest llat.....℥ ij.
M. Sig. A teaspoonful at a dose.

ECZEMA OF THE VULVA.

Dr. Lusch (*L'Union Médicale du Canada*, No. 9, 1891) speaks highly of the following:

℞ Sodii bicarbonat.....grammes 4.
Potassii bicarbonat..... " 2.
Glycerin neutr..... " 3
Tinct opii..... " 4.
Aquæ..... " 175.
Apply locally, and then dust on—
℞ Amyl. pulverizat..... " 98.
Camphor pulverizat..... " 2.

ACUTE ECZEMA.

Dr. Alexinski (*La Semaine Médicale; L'Union Médicale du Canada*, No. 9, 1891) uses the following:

℞ Zinci oxydat.....grains xv.
Bismuthi subnitrat..... " xxx
Amyl. pulverizat.....℥ jss.
Lycopodii pulverizat.....℥ jss.
Dust in on the parts affected nights and mornings.

SALOL AS A COATING FOR PILLS.

In consequence of the fact that Salol is not dissolved in the stomach, but is only attacked by the pancreatic juice after it reaches the intestine, Dr. Ceppi suggested its use for coating pills intended not to act *before they enter the intestines*. Dr. Yvon publishes (*Union Pharmaceutique*) the following formula for the purpose in question:

Salol.....grammes 2.
Tannin..... " 0.5.
Ether..... " 10.

With this solution the pills are varnished several times, until the protecting layer is sufficiently thick. The entire operation—Dr. Yvon states—does not occupy more time than is required in varnishing wiih Tolu Balsam.

TREATMENT OF FAVUS.

Dr. Kerley (*La Semaine Médicale*, No. 53, 1891), in the treatment of favus, employs the following:

1. ℞ Hydrarg. corrosiv.....centigrammse 12.
Alcohol, q s.,
Petrolei, } .....ää grammes 15.
Ol. olivar, }

2. ℞ Alcohol absolut.....grammes 30.
Iod. pur., q. s. to obtain a saturated solution.
For external use.

Sponge and rub the favus spots and the adjacent surrounding skin one day with the first solution and the next with the iodine solution. Continue until a slight irritation of the skin supervenes, then interrupt the treatment a few days and apply an indifferent salve, when the treatment may be recommenced

The writer asserts that a case of favus may thus be cured, on an average, in six and a half weeks.

BLOOD POISONING.

℞ Eucalyptol (Sander)..... ½ ounce
Syrup simplex.....1½ ounces.
Aqua.....2 "
One teaspoonful every one or two hours.

CHOREA.

Benedikt recommends the following treatment:

℞ Fowler's solution .....2 to 3 parts
Distilled water.....222 parts.
Simple syrup..... 30 "
M. Sig. Tablespoonful three times a day.

If there exist articular pains, give sodium salicylate for some days. Apply the continuous current along the vertebral column. Avoid narcotics, particularly hydrate of chloral. Desnos has used exalgine with marked success.—*Medical Abstract, June, 1891.*

LEADING ARTICLE.

ELECTROTHERAPY.

So much has been said recently in medical literature on the subject of electrotherapy, and so vast is the amount of conflicting evidence brought to light by able exponents of both sides of the question, that the subject is one that should be approached with caution.

Foremost among the most recent dissertations on this subject is the article contributed to the *Progrès Médical* in one of its recent numbers, and which has also been discussed in other French medical journals, notably the *Revue Médicale.*

The writer of the article alluded to, Dr. Vigouroux, deals with the subject broadly and succinctly, basing his conclusions both on extended personal observation and a careful review of the experience of others. He refers to the three principal methods for the application of electricity: *Faradism, galvanism,* and *static* electricity or *franklinism.*

Faradism consists in the employment of an induction current, viz., an interrupted current; galvanism of a continued current; and static electricity or franklinism, of a current produced by the so-called electric machines of Ramsden, Holtz, Carré, Winshurt, etc., by which the electricity is generated through friction.

There are important differences in these three methods of applying electricity. In the first two generally but a part of the body of the patient is placed in the circuit between the two poles, while in franklinism, the patient being isolated from the ground, represents a continuation of one pole of the machine, the current being diffused through the entire body. In consequence, faradism and galvanism are essentially applicable for local medication, while franklinism may be found more useful in general medication, but has also a field of usefulness in local use.

Another fundamental point of difference between these three forms of electricity lies in the potential quantity (tension) of each. In this relation we find galvanism and franklinism radically different from each other. The

potential quantity of electricity in galvanism is never above a voltage of 50 or 60, while in franklinism it is very high, ranging from 100,000 to 150,000. The strength of the current is in inverse proportion to the voltage; thus, in franklinism an extremely high voltage produces a weak current, while in galvanism a very low voltage produces a far more powerful current, this being occasioned by an increased amperage. In consequence, while the static current does not exert any pronounced chemical or magnetic action, its mechanical action is very marked; and, on the contrary, the chemical and magnetic actions of the galvanic current are relatively more intense. The induction or faradic current occupies a place between these two.

Therapeutically, the galvanic current will be found to produce, locally, chemical, physiological, and mechanical actions.

Regarding the chemical effects, these consist of supposed chemical decompositions in the fluids of the body, termed *electrolysis.* The bases and hydrogen approach the negative pole, while the acids and oxygen are attracted to the positive pole. Vigouroux, however, very positively asserts that under ordinary circumstances, chemical or electrolytic actions are not observable. The mechanical effects consist in a displacement of liquids in the course of the current.

It is the physiological action that is most important, and this is manifest in the phenomena of excitation. All organs and excitable structures react in some form according to their specific properties, such reaction continuing as long as the electric current is applied. In order to obtain these results it is necessary that the current is interrupted with sufficient frequency.

The difference of the actions of electricity at the two poles is very noticeable. At the negative pole we find an afflux of liquids, hyperæmia owing to dilation of the blood vessels, and an increased excitability of the nerves. At the positive pole the conditions are directly opposite: anæmia caused by contraction of the arterioles, reflux of liquids, and a diminution of the excitability of the nerves.

Practically, therefore, the physiological actions of the two poles are in opposition to each other; the negative pole congests and excites, while the positive pole depletes and depresses.

Apart from these, electricity exerts a general action, which is commonly partially or entirely overlooked, and which consists principally in an increased activity of calorification and respiration, and, finally, in a sensation of well-being—euphoresis—indicating a widespread action on nutritive processes.

This general action, while almost *nil* in galvanism, is more marked in faradism, and reaches its maximum in franklinism.

The electrical current should, in all cases, be applied by the physician himself, and for this purpose it is by no means essential that he should be a specialist.

Regarding the therapeutic application of electricity, Dr. Vigouroux has limited himself exclusively to the nervous system. While a detailed account of his experiments would prove interesting reading, we are forced to content ourselves with a brief recapitulation of his results.

There is nothing to prove that when electricity is applied to the head in the ordinary manner, this organ is in any way affected by the current. The various phenomena that are apparent during the application of the current, such as a metallic taste, ringing in the ears, and vertigo are all explainable by an excitation of the nerves of sense, or other indirect actions. The only possible way in which the brain might be influenced is through a reflex action.

In diseases of the medulla, the author found that this organ, like the brain, was unaffected by electricity.

In neuroses, in the treatment of hysteria and neurasthenia, the principal treatment is to improve general nutrition; for if we treat these conditions locally, by electricity, we are more apt to set up a condition worse than that of the original malady. In children, for instance, hysteria is often manifested in the form of contractions, etc.

In children the general treatment of these neuroses should consist in franklinism, to the

entire exclusion of hydrotherapy, but coupled with cautious internal medication.

In chorea in children, especially the type which is frequently followed by relapses, franklinism will frequently be found most useful.

In "tics," true "tic" is incurable by electricity, as well as by other means. Pseudo or false "tic" is easily conquered by franklinism.

In progressive myopathies, atrophic or pseudo-hypertrophic, electricity is only valuable as a means for diagnosis.

In muscular atrophy, consecutive to arthritis, viz., simply atrophy (resulting in long immobilization of a limb consequent to a fracture or some other injury) and amytrophic spasmodic paralysis. The treatment should consist of franklinism, applied both generally and locally, to the affected muscles.

Good results are seldom attainable in atrophic paralysis. Most frequently the application of the current is entirely ineffectual.

In infantile paralysis, multiple neuritis, or acute polyneuritis, little is to be gained by electricity.

In the local treatment of the majority of peripherical paralyses electricity is certainly useless, and often absolutely harmful.

In conclusion, Dr. Vigouroux is of the opinion that electricity is entitled to a prominent place in therapeutics, but that its use should always be undertaken with caution.

SALT LAKE MEDICAL SOCIETY.

The annual meeting of the Salt Lake Medical Society was held in the Chamber of Commerce Hall. There was a large attendance of the members.

The following officers were elected: Dr. G. W. Foster, president; Dr. S. Ewing, vice-president; Dr. E. F. Root, recording secretary; Dr. J. C. E. King, corresponding secretary; Dr. J. J. MacAckran, treasurer; and Dr. Union Worthington, librarian.

The treasurer reported that there was $168 in the treasury.

Other reports which were read showed that there was an enrollment of fifty-two members and that new members are constantly being received.

BOOK REVIEWS.

SAUNDERS' QUESTION COMPENDS, No. 23. ESSENTIALS OF MEDICAL ELECTRICITY by D. D. Stewart, M. D., Demonstrator of Diseases of the Nervous System and Chief of the Neurological Clinic, in the Jefferson Medical College; Physician to St. Mary's Hospital, etc.; and E. S. Lawrence, M. D., Chief of Electrical Clinic and Assistant Demonstrator of Diseases of the Nervous System in the Jefferson Medical College; Physician to Dispensary of St. Christopher's Hospital for Children, etc. Cloth, with 65 illustrations. Price, $1.00.

This number of the series of compends recently issued by this publishing house is certainly one of the most useful, and treats of a subject which is generally much neglected in the education of medical students. It will undoubtedly prove a practical help to the practitioner also, and its size will render it a valuable addition to any doctor's library, containing as it does, much practical knowledge of a wide subject in a very small compass. During the last few years the tendency has been to print too many of these quiz-books, but the present one should fill a "long felt want" because it presents in a readable form a concise synopsis of a subject not often treated in this class of works. We take pleasure in recommending it to the profession generally, and to the student in particular.

THE RATIONAL CURE OF DEAFNESS AND DISCHARGES FROM THE EAR. The Modern Treatment for the Radical Cure of Deafness, Otorrhœa, Noises in the Head, Vertigo, and Distress in the Ear. By Samuel Sexton, M. D., author of "The Ear and its Diseases," etc., etc.; Assisted by Alexander Duane, M. D., New York: J. H. Vail & Co., 1891.

The reputation of the chief author of this communication upon the radical cure of deafness and discharge from the ear is sufficient proof that it will receive a wide reading at the hands of the profession. Apart from this fact, however, the subject dealt with is an extremely important one, and the clinical experience which is detailed in the book adds greatly to its force. It consists of a reference to the old operation for relief of these troubles, with remarks upon the reasons why it failed to be of permanent benefit, and followed by a clear and concise description of the operation as practiced by Dr. Sexton, succeeded by a consideration of the indications for the operation. The authors contend that in all cases of chronic catarrh of the middle ear, attended by deafness, unpleasant noises, etc., it has proven in their hands a permanently curative procedure; and they detail cases illustrating its good results. The

subject matter of the book is chiefly taken from former papers by Dr. Sexton, while many details regarding indications for treatment and operation are wholly new. It is an attractive little book, exceedingly well written, printed in very readable type, and combines in a few words the essential points of an extremely important subject.

LITERARY NOTES.

A pathetic interest attaches to the volume of *Lyrics*, by Cora Fabbri, about to be published by Harper & Brothers. The very spirit of youth and love and spring breathes through these sweet verses, which have a dainty finish and grace worthy the muse of Italy. It is difficult to think of their author as out of this bright world, but, alas! Cora Fabbri died at San Remo, on January 12th. An advance copy of her poems was sent to her early enough, it is to be hoped, to have given her a passing pleasure.

A STUDY OF THE MYSTERIES OF LIFE.

In a world where it is very desirable to be entertained, and not always easy to find entertainment, there is a great deal to be got out of a discreet consideration of the mysteries of life. They give one something to theorize about in odd moments, and to have theories about them gives one an interest in whole series and classes of facts which seem to fit in with such theories or to upset them. If the facts won't fit the theory, then there is the theory to change; and to have one's theory driven into a new shape is the next best thing having it justified.

There was a little tale in the newspaper the other day about Mr. Edison, that he held up his finger and bent it, and asked, "What does that?" Failing to get a satisfactory reply, he said he was trying to find out what is the force that pulls the strings that make animate creatures move. That is one of the great mysteries—the mystery of motion. It is that, we are told, that Mr. Keely, the motor-man, has been brooding over for several decades past. Mr. Keely's experience has not been such as to encourage any poor men theorize on this subject for a living; nevertheless, it is a great subject for a mind to dwell upon in its leisure moments. Sir Isaac was thinking about it when the apple fell and gave him an idea that was of value to him, and has been useful ever since. There is always this advantage about having one's mind run on something in particular, that even if it does not bring down what it is aimed at, it is more likely to hit something else that is worth while than if it was wandering aimlessly.—From "The Point of View," in February *Scribner*.

THE complete novel in *Lippincott's Magazine* for February, "Roy the Royalist," is by Mr. William Westall, and is a stirring tale of adventure in the wars of Napoleon. Though its events date back nearly a century, they are presented in the brisk and business-like modern manner. The hero, a dashing young officer of the British navy, prompt and capable alike in friendship, love, and war, meets Bonaparte while a prisoner in France, distinguishes himself in the defence of Acre, recovers a treasure concealed in a château of the Jura by its *ci-devant* owners, and finally settles in his native Virginia.

PERISCOPE.

THERAPEUTICS.

TREATMENT OF HEADACHE OF GASTRIC ORIGIN.

Dr. Westphalen (*Berlin klin Wochenschr.*, No. 37, 1891,) discusses headache of gastric origin. He refers at the outset of two cases observed by him in connection with Dr. Moritz, and published by the latter. Although these patients did not suffer from headache, but were the subjects of obstinate intermittent fever, combined with skin eruptions resembling erythema nodosum, their cases are included in the present paper because Dr. Westphalen is of opinion that such symptoms are of gastric origin; that, in fact, toxic substances present in the stomach under certain circumstances are capable of producing, after absorption, various skin eruptions and disturbances of temperature on the one hand, and, on the other, disturbances of circulation in the central nervous system and its associated parts, a consequence of which is headache. In the two cases referred to attention was drawn to the stomach by slight dyspeptic trouble. The conclusions having been come to that the general disturbance was due to absorption of toxic material from the stomach, an indication presented itself in the fact that, in one of these cases, there was complete absence of hydrochloric acid from the contents of the stomach. The acid was prescribed in both cases; the fever and skin eruption disappeared, and the patient completely recovered. The author explains the success of the drug on the theory that the ptomaines or toxines of micro-organisms are

capable of exerting their detrimental influences only when there is a deficiency in the amount of free mineral acid in the stomach. The antiparasitic action of the normal gastric juice may be taken as proved in the case of certain species of bacteria at any rate. To the two cases first reported three others are now added. In one the skin affection present was erythema exudativum multiforme, in the other two urticaria. All were cured by hydrochloric acid. In one of the urticaria cases the outbreak was apparently prevented by this drug. The patient who suffered regularly from urticaria, accompanied by giddiness and a feeling of congestion in the head after eating strawberries, was induced to eat a quantity of them, and to take twenty drops of dilute hydrochloric acid fifteen minutes afterwards. The symptoms failed to appear.

The author next gives details of four cases of unilaterial headache associated with dyspepsia and following upon errors of diet. The patients had taken many drugs, such as antipyrin, antifebrin, caffein, phenacetin, without benefit; muriatic acid caused the headache rapidly to disappear. Further treatment consisted in the regular administration of the acid in association with mineral waters, and attention to the diet. Three of the patients recovered, whilst the fourth was materially benefited. In two of these cases also the headache was apparently prevented by the administration of the acid directly after the patient had eaten freely of some article the ingestion of which had hitherto been invariably followed by headache. Whilst believing that in very many cases the symptoms (headache, skin eruptions, fever), may with much probability be referred to the action of some poisonous product of bacteria, Westphalen remarks that in certain cases the nature of the noxious substance is obscure, as, for example, in those in which the symptoms mentioned follow the ingestion of such articles as chocolate and strawberries. But in the last class of case, also, muriatic acid is efficacious.—*Brit. Med. Jour.*

TREATMENT OF OZÆNA.

Dr. Demme states in the *Deutche Medicinische Wochenschrift* that he had found massage of the nasal fossæ the best treatment for ozæna, and one followed by good results in a very short time. The object is to produce a hyperæmia which is of an acute character, it having been observed that ozæna is frequently cured by a new acute rhinitis. The method of procedure is as follows: A metal sound has a wad of cotton wrapped around it at its extremity, the wad being about as hard as the pulp of the finger. A 20 per cent. pyoktanin lanolin ointment is employed. The movement consists of light, short, even strokes which resemble effleurage. This sitting should be of daily occurrence and last not more than one-half minute for each fossa. In many cases two sittings a week are sufficient. One pre-requisite is absolute cleanliness in the operation. The touch dispenses with the necessity of using a mirror, and in some of the more intelligent patients the author found that they could perform the massage themselves. He claims that a cure is effected in a few weeks.

PILOCARPINE FOR DRYNESS OF THE TONGUE.

Gelatine capsules containing from .003 to .006 grm. of pilocarpine are recommended to relieve dryness of the tongue. One of them is permitted to desolve on the tongue previously wetted with water. This causes a free flow of saliva for twenty-four hours, while it never produces any diaphoresis.—*Jour. Med. Par Revue Int. Bib.*

THE TREATMENT OF SCROFULODERMA AND LUPUS.

Dr. Brooke has somewhat modified the method of treating lupus by an ointment of oleate of mercury, salicylic acid, and ichthyol, which he published a year since. Finding in some cases the original formula too strong, he has reduced it, combined it with Lassar's paste, at the same time adding sufficient red Armenian bole and raw umber to match the color of the skin.

℞

Zinci oxidi, Amyli pulv.	āā ¼ oz.
Vaselini albi	½ oz.
Hyd. oleatis, 5 per cent.	1 oz.
Acidi salicylici	gr. xx
Ichthyolis	℥ xx
Ol. lavendulæ	q. suff

M. fiat ung. coloratum.

This, when well rubbed in and then covered with potato-starch powder, completely disguises the disease, and attracts very little attention. He sometimes diminishes the salicylic acid and increases the ichthyol. The action is most rapid in cases of scrofulodermic tumors and ulcerations, but is also pronounced in those in which lupus has developed from the scrofulodermic basis. In pure lupus the effect is distinctly weaker, especially in those where there is much sclerosis or old scarring.—*British Journal of Dermatology*, December, 1891.

CHRONIC DIARRHŒA.

Dr. Alexejewski (*Deutsche Medizinal Zeitung*, July 2, 1891) has found the flowers of the red rose to have long been held in high repute amongst the Russian peasantry as a remedy in chronic diarrhœa. He uses an infusion made with a handful of the dried flowers. Children up to five years may take during the course of a day a cupful.

A CASE OF IODISM.

A case came under my observation a few days ago which so well illustrates the ease with which an error is committed in a syphilitic subject that I cannot forego reporting it. I was in the act of leaving St. Mary's Hospital, having completed my visits to patients, when I was asked to see a young man in the waiting room who had applied for admission. I found a youth of about 20, well nourished, and of good muscular development. His appearance was that of health, except that his color was rather dusky, his eyelids puffy, the conjectivæ injected, and there was some swelling of the right orbital region. There were also a half dozen cicatrices on the face, one of them on the chin, another on the side of the nose, a third involving the eyebrow, each of them a half inch in diameter, flat and white. The patient complained that he had suffered for a month from a frontal headache, gradually increasing in severity, of the swollen condition of his face, and of some tenderness of the frontal bone. Weakness was the only other symptom complained of, and this, the patient alleged, caused him to quit work and come to the hospital. He admitted having had a "bad case" of syphilis one year ago. There was no perceptible coryza. Without further examination, I recommended him for admission, and asked that he be given fifteen-grain doses of potassium iodide until I made my next visit.

Next morning I approached my patient in full anticipation that I would find in him an interesting case, some freak of constitutional syphilis, which would rapidly fade away under heroic doses of the iodides. But I found his condition so much worse than it had been the day before that I at once suspected the existence of iodism. I then learned that the patient had been under the treatment of a druggist—enough to account for any conceivable catastrophe.

All treatment was suspended, and in three days the patient was dismissed entirely cured.—*James M. French, in Jour. Med. Coll., Ohio.*

RHUS AROMATICA IN THE TREATMENT OF INCONTINENCE OF URINE.

In the *Buffalo Medical and Surgical Journal*, October, 1891, Dr. Wm. C. Krauss, of Buffalo, sums up his experience in nine cases as follows:

Incontinentia urinæ, due to slight disorders of the genito-urinary or nervous systems, is amenable to the rhus treatment, and gives most favorable results.

Incontinentia urinæ, due to destructive lesions of the spinal cord, complicating the vesical centre, or its reflex arc, is not amenable to the rhus treatment, and gives negative results.

BENZINE IN PEDICULOSIS.

Nedzwiecki strongly recommends (*Saratovsky Sanitarnyi Obzor*, No. 19, 1891) ordinary commercial benzine as the most effective, cleanly, and convenient application for destroying pediculi capitis or pubis. The affected parts should be freely bathed with the fluid for three or four minutes. Both pediculi and nits are killed almost instantaneously. As a rule, a single application is sufficient, even in severe cases. The smell of benzine is said to disappear very quickly. The remedy can be safely applied, even in the presence of an eczematous rash, since it causes only trifling pain, which soon passes off. In the case of out-patients, the treatment must always be carried out in the day time, as the substance is extremely inflammable.—*Brit. Med. Jour.*

HYDRATE OF AMYLENE IN EPILEPSY.

Dr. Edwin Dunn has given a trial to this remedy, recommended by P. Naecke for epilepsy. He gave it to fourteen patients for twelve weeks, in half-drachm doses three times a day for the first four weeks, and for the remainder of the time four times a day. Twelve of the patients had been previously under the treatment with bromide of potassium. In three the number of fits was increased; in four the number diminished; and in three the number remained the same. Two died in a status epilepticus, one in the first week, the other in the twelfth. Of the two patients not previously treated, in one the drug had no effect, in the other the number of fits was diminished by one-third. During the early weeks of treatment there was a marked improvement in the mental state, but this is probably due to the leaving off the bromide, for after the first month there was a marked tendency for the patients to

pass into a status epilepticus, and in no case ultimately was the mental condition of the patient improved. There was no change one way or the other in regard to bodily condition. He concludes that it was perhaps beneficial in some of the less severe cases, but that in the graver forms it was useless, and that it possesses no advantage over the ordinary bromide treatment.—(*Journal of Medical Science*, October 1891.)

STERILIZATION OF MEDICINES FOR HYPODERMIC USE.

On making gelatine plate cultures from the more commonly-used hypodermic solutions, Dr. Marinucci reports in *Riforma Medica*, October 25th, that some, especially those of eserine and morphine, were teeming with bacteria. He next proceeded to test the effects of sterilization on the above solutions, the method employed being either to boil them or to expose them for a time to a temperature of 100° C. in a Koch's steam sterilizer. He then tested the activity of the solutions thus treated as compared with the same before sterilization, and came to the following conclusions: In all the preparations studied there may develop microbes, of which, however, probably not all are harmful. Sterilization by heat does not alter solutions of strychnine, curare, bi-hydrochlorate of quinine, or borate of eserine; enfeebles but does not alter the character of the action of morphine and atropine, so that the sterilized liquids must be used in larger doses than the non-sterilized ones; it seriously alters sulphate of eserine, rendering the solutions in great measure inert. The solutions unaffected by heat may be sterilized simply by boiling for a time in a *bain-marie*. It is recommended also to sterilize the hypodermic syringes in the same manner. For those solutions which are found to be altered by heat, an excellent method of keeping them sterile is to add corrosive sublimate in the proportion of 1 to 10,000. This is perfectly efficient, and is in no way harmful to the active drug.—*Boston Med. Surg. Jour.*

TREATMENT OF INTESTINAL OBSTRUCTION.

Washing out of the stomach, as first recommended by Kussmaul, in intestinal obstruction, is regarded by Aufrecht as a useful addition to our therapeutic measures. The difficulty is to determine in which cases and under what circumstances it should be carried out, as it is not equally applicable in all cases. On the ground of experience Aufrecht recommends two special indications. The first and most important of these is distension of the stomach, where vomiting is not present or has ceased suddenly. It is estimated that this condition is seen in about one-fifth of all cases of ileus, and its recognition may be made by percussion, the extended deep full note distinguishing it from a distended colon. The absence or cessation of vomiting is often looked upon as being due to the œsophagus being folded over the opening in the diaphragm, and its lumen blocked. However that may be, introduction of a tube takes place without difficulty, and evacuation of a large amount of fluid gives great relief, often without any washing out. A further indication is the occurrence of feculent vomiting. Repeated cleansing of the stomach removes the abnormal contents, and prevents the absorption of injurious material. Aufrecht pleads for the use of morphine in all cases—used subcutaneously. It should be given three or four times daily, according to need, until the patient is free from pain and peristalsis is kept within bounds. Its use by the mouth should be discontinued, its action not being prompt, and the amount absorbed uncertain. Large injections into the bowel he has long ago given up. Only in the very early days can one hope to obtain any useful result. He tried intestinal puncture on two occasions, but no particular good was observed, and he was dissuaded from continuing it by peritonitis being set up in one of the cases.—(*Therapeutische Monatshefte*, part viii. 1891.)

MEDICINE.

DEGENERATION OF THE SOLAR PLEXUS IN THE INSANE.

Several experimenters have found that by inducing lesions of the solar plexus in animals they were able to produce glycosuria, acetonuria, and albuminuria. A knowledge of these results led Dr. Cristiani to see whether the same abnormal substances occurred in the urine of mental patients suffering from degeneration of the solar plexus, a lesion which has been found by him to be evidenced by a so-called "vaso-paralytic diarrhœa." (*Riforma Med.*, September 17th, 1891). This triad of symptoms, if it were found to occur constantly in such patients, would be a valuable aid in the diagnosis and prognosis of this form of diarrhœa. With this object the author undertook the examination of the urine of 10 such patients, comparing the results with others obtained in 15 cases of simple intestinal catarrh and in a similar number of patients without diarrhœa. The

results are as follows: Glycosuria and albuminuria were found in all the first 10 patients, but were absent in the 30 others examined as controls. From a large number of observations by the same author these two signs seem to be very rarely present in asylum patients not suffering from nervous diarrhœa. Acetonuria, which is a constant and lasting phenomenon after experimental lesions of the solar plexus in animals, was entirely absent in the cases observed. As regards the glucose and albumen, either one or the other or both together, would be found on various occasions. In regard to the period of the disease, these symptoms were inconstant as to time of appearance or duration. The fact remained, however, that in the patients with diarrhœa originating in solar disease they were sure to be discovered sooner or later, if daily analyses of the urine were made, while in the urines of the others no such abnormal products were discoverable.—*Brit. Med. Jour.*

CEREBRAL ACETONÆMIA.

Talamon, in an interesting paper, states that a group of nervous symptoms comparable to those of uræmia has been described under the name of acetonæmia, a condition characterized by a reddish color imparted to the urine on the addition of perchloride of iron, and by the peculiar acidity of the breath, which exhales an odor that has been compared to that of chloroform, and which in reality is the odor of acetone or of ethyldiacetic acid. Various observers have concluded that the nervous symptoms were due to acetone acting upon the organism in the same manner as chloroform. The precise pathogeny of this toxæmia, however, has not been chemically elucidated any more than has that of uræmia or cholæmia. The substance which with the perchloride of iron causes the red reaction in the urine may be ethyldiacetic acid (Gerhardt) or diacetic acid (Jaksch). The symptoms of poisoning may result, not from the isolated action of one of these substances, but from a series of chemical decompositions, of which the acetone and diacetic acid are but ultimate products of little importance. Acetonæmia has especially been observed in diabetes and in diabetic coma. Peters and Kaulich have, however, noticed that the odor of the breath and the reaction of the urine are observed not only in diabetics, but also at times in the course of the eruptive fevers in children with measles and scarlet fever.

The searches of Jaksch have confirmed this observation, and have shown that normally the blood and the urine always contain traces of acetone, the quantity of which may be increased in the anaxthemata and in different chronic maladies, particularly carcinoma. Jaksch recognizes three varieties of acetonuria—the diabetic, the febrile, and the carcinomatous. According to him the nature of the febrile process is a matter of indifference. He has noticed this symptom in pneumonia, in typhoid fever, in acute articular rheumatism, and in the eruptive fevers. He has even observed pronounced acetonuria in a case of mania without fever. Acetonuria and diaceturia may thus exist without acetonæmia; in other words, the red reaction of the urine with the perchloride of iron may be produced in the absence of symptoms of acetonic toxæmia. Talamon relates the case of a girl of fifteen with a history of an attack of acute articular rheumatism with endocarditis. On the fifth day the temperature reached 105.8°, and the girl presented a condition of marked nervous excitement and delirium, this being characterized by incessant agitation and terrifying hallucinations, and accompanied by an odor of acetone in the breath and a ruby read reaction of the urine with the perchloride of iron. The delirium lasted five or six days, and disappeared synchronously with the disappearance of the odor of acetone in the breath. From a study of the case reported, and from a review of the literature of the subject, Talamon concludes: 1. Certain of the nervous phenomena that appear in the course of acute febrile diseases may be attributed to acetonæmic intoxication. 2. These acetonæmic phenomena are characterized by the peculiar odor of acetone in the breath and the ruby-red reaction that the urine presents with the perchloride of iron. 3. The delirious acetonæmia of articular rheumatism may simulate cerebral rheumatism, from which it is to be distinguished by the absence of hyperpyrexia and by the characteristics of the urine and of the breath. —*Lancet.*

REAPPEARANCE OF EPIDEMIC INFLUENZA.

Recent reports from widely separated countries show that there is considerable prevalence in scattered areas. From special inquiries which we have made we learn that influenza has been prevalent in Dundee since the second week in July, causing, we are informed, two or three deaths monthly, but since the beginning of the present month it has spread rapidly. A large proportion of the time of medical practitioners in the city

has been devoted to these cases. Whole families of five and eight persons have been laid up at one time. The only complications so far have been bronchitis and excessive prostration with a prolonged period of loss of appetite and want of energy. The epidemic has also appeared in Galicia, introduced, it is said, from Russian Poland and Russia. "Thousands" of cases are stated to have occurred in Lemberg and other Galician towns, and a few in Vienna. The epidemic is reported to be severe in Prussian Silesia, 500 cases and several deaths having occurred in the town of Münsterberg alone. Epidemic influenza is also said to have broken out in Paris during the past week. Advices from Victoria state that the disease is rife in Melbourne and has spread to the country districts. —*Brit. Med. Jour.*

PYREXIA AND ANTIPYREXIA—NERVOUS AND ARTIFICIAL.

Richter (*Inaug. Diss.*, Breslau, 1891), gives an account of some experiments made by him on pyrexia and antipyrexia. He first of all discusses the mechanisms by which the temperature can be lowered, and concludes, as a result of calorimetrical experiments upon animals in which fever had been artifically induced by the injection of infusion of hay, that fever consists in a shifting of the heat regulation mechanism. He therefore adopts Filehne's theory of fever. The difference between a nerve temperature and fever is next discussed, and the author does not believe that there is in the brain any heat centre of damage which can cause fever. He regards the pyrexia which may be brought about by damage to the corpus striatum as quite distinct from fever, being only a temporary disturbance of the heat-regulating mechanism.—*Brit. Med. Jour.*

WARM ETHER AS AN ANÆSTHETIC.

We learn from the *Independencia Medica*, of Barcelona, that on October 31, Dr. Giné y Partagás performed an operation for osteoma of the fibula on a woman, in the Hospital de Santa Cruz, of that city, the anæsthetic used being ether warmed to 31°C., which was administered by Dr. A. Diaz de Liaño, with an apparatus of his own invention. Anæsthesia was rapidly induced and was kept up for fifty-five minutes without any accident. The temperature of the ether remained at 31° nearly to the end, when it fell to 29.5°. The apparatus, which is called by its inventor an "Electrothermo-etherizer," has since been used in several other cases with equally satisfactory results, anæsthesia having, on one occasion, been kept up for two hours and a half without any ill effect. Dr. Diaz de Liaño claims that by his method the disadvantages both of cold ether and of chloroform are obviated. Our contemporary promises a full description of the apparatus at an early date.—*Brit. Med. Jour.*

SURGERY.

TREATMENT OF OLD ULCERS OF LEG.

Dr. Charles P. Elwert, of New York, writes the *Medical Record:* "I have treated in the past six months, at Demilt, Bellevue, and Vanderbilt Dispensaries, and also in my private practice, forty-six cases of varicose and other ulcers of the leg, and have obtained favorable results in thirty-four cases, by the following method: Cleanse the ulcer by irrigating with a solution of corrosive sublimate, 1 to 5000. Then dry thoroughly with absorbent cotton, and apply daily the following powder:

℞

Iodoform	ʒ ss.
Sulphate of cinchonidia	ʒ j.
Wood charcoal	ʒ ijss.

If any discharge appears after applying the powder, use absorbent cotton before applying the powder again, Advise the patient to rest and to keep the leg elevated. Keep the bowls regular with a mild laxative, and give some stimulating tonic to improve the condition of the general system. In the case of four patients the powder caused irritation, and the discharge was increased. On further examination of those patients I discovered the existence of Bright's disease. In six other cases, where the above treatment was not successful, a poultice composed of powdered wood-charcoal and matricaria was used for three or four days, until I obtained a healthy appearing surface to the ulcer; and I then applied daily the following solution:

℞

Tr. calendulæ	ʒ ij.
Aquæ champhoræ	ʒ viij.

After applying the solution, I strapped the ulcer with adhesive plaster, with good results in four of the above six cases, and gave laxatives and a tonic. As the treatment of chronic ulcers at the present day is not very successful in a large percentage of cases, especially in dispensary practice, the above treatment may be of use to the profession."

UNION OF CUT-OFF FINGERS.

Herr Gluck related among other things which he brought up before the Berliner Medizinische Gesselschaft (*Deut. Med. Zeit.*), the case of a butcher who cut off the distal phalanges of his middle and ring fingers with a cleaver. The reporter, forty minutes after the accident occurred, picked up the severed fingers from the floor, disinfected them, resected the bones and sutured carefully. A complete union took place. Sensation, however, only returned in six months. A difference in the length of the fingers which were injured, and those of the other hand could not be perceived. However, a certain amount of atrophy was observable in the ends which had been severed.

SPIRITS THYMOLINI, COMPOSITUS—A SUBSTITUTE FOR LISTERINE.

C. D. Lippincott writes (*Phar. Rev.*): Listerine, as introduced by Dr. Lambert, is a step in progressive pharmacy. This new antiseptic disinfectant and prophylactic has become popular in nearly all civilized countries. While a mechanical mixture in itself, it exhibits the manifold properties of its constituents, and occupies a prominent position in the long catalogue of medico-surgical and therapeutic agents of modern practice. While we justly admit we are indebted to Dr. Lambert for its introduction, yet as professional pharmacists we do not feel like being confined to the necessity of dispensing empirical or proprietary preparations; hence it behooves us to come to the front with a substitute, which we all may manufacture and which will, beyond doubt, prove equally efficacious in its object. Such a preparation I herewith respectfully submit for your careful consideration, and invite research and experiment, with a view to possible improvement of this formula. I also recommend the adoption of a definite term for such a preparation. To me the term Spirits Thymol Compound would not be inappropriate, conveying, as it does, an intelligible meaning to physician and pharmacist. The Lambert Pharmaceutical Company, of St. Louis, place their formula upon each bottle of their preparation as follows. They say: "Listerine is the essential antiseptic constituent of thymol, eucalyptus, baptisia, gaultheria and mentha arvensis, in combination. Each fluid dram also contains 2 grains of refined and purified benzo-boracic acid." Given internally, they advise one teaspoonful three or four times a day, either full strength or diluted with water, or in combination with other drugs. My formula for what, for the present, I will call Spirits Thymol Compound, is as follows:

℞

Acid benzoic, Sodium biborate	of each	ʒ i grs. xxxii
Boric acid		ʒ ii grs. lxiv.
Dissolve with the aid of heat in distilled water		ʒ xlviii

Then add

Thymol		grs. clx.
Eucalyptol, Oil of wintergreen	of each	drops xl.
Oil of peppermint		drops xxiv.
Oil of white thyme		drops viii.
Previously dissolved in alcohol (94 per cent.)		ʒ xxiv.
Mix the two solutions, add caramel		drops x.
Distilled water q. s. to make 1 gallon.		

Let the mixture stand 24 hours, and finally pass through a wetted filter.

OBSTETRICS.

TOBACCO IN OBSTETRICS.

Some practitioners take their *rôle* in the lying-room very much *au sérieux*, and act as if they considered themselves personally responsible for any little hitch in the arrangements, with the result that the parturient female is occasionally subjected to treatment which is, to say the least of it, startling. We cannot better illustrate the point than by a recently-published contribution from the pen of Dr. J. F. Bird, of Philadelphia. He relates having been called to a case of labor which resisted all the usual means of bringing about the dilation of the os. The labor was at full term, and the pains were excessively severe and regular. At his first visit he bled the patient, *horresco referens*, to the extent of sixteen ounces without the slightest effect. For the ensuing twenty-four hours he administered antimonials *ad nauseam*, with no better result. He then opened a vein in the arm, and again drew blood, *pleno rivo*, still producing no relaxation, although he carried the bleeding "as far as was consistent with safety." This resourceful practitioner's next inspiration was the pipe, and his patient had been smoking but a short time before nausea occurred, an din twenty minutes the dilatation was complete, and the child was expelled immediately, and in good condition. The success which attended his experiment on this occasion induces him, twent-five years after date, to urge upon his brethren to include a couple of cigars (quality no object) in their obstetrical armamentarium. He affirms the effect to be "magical" and "highly gratify-

ing." It is of course to be understood that such effects can only be obtained in women who are not acclimatized to the weed, but we gather from Dr. Bird's remarks that some of his patients took very kindly to the innovation both then and afterwards. Most doctors do not go further than themselves to smoke the pipe, but in future we may anticipate that patients will insist upon undergoing the treatment, and will decline to admit the *quid fecit per alter fecit per se.—Méd. Press.*

PRURIGO IN CHILDBED.

Krastilefsky (*Nouvelles Arch. d'Obstêt. et de Gynéc.*, October, 1891, Supplement, p. 457) has recently published, in a Russian paper, a case where a woman, who had borne fifteen children, suffering on each occasion, from a week before delivery to the second day of childbed, from a general idiopathic prurigo. No cause could be discovered for the cutaneous trouble. Great relief was afforded by hot baths, and by a lotion composed of carbolic acid 4 parts, glycerine 30 parts, and distilled water 180 parts.

IMPREGNATION FROM SEMEN DEPOSITED ON THE VULVA.

R. C. Longfellow, *Cincinnati Lancet Clinic*, 1891, p. 633, saw patient who denied ever having indulged in sexual intercourse. Her companion afterwards gave Dr. Longfellow the following particulars: "Some three and a half months before, he had attempted to introduce the penis in the vagina. It was impossible to do so on account of the pain given to the lady, but soon an emission of semen occurred on the vulva. Soon after they left his office without making any toilet, the semen being allowed to remain on the vulva over night. This only occurred once between them, and the next menses did not appear, as also the second and third, which was attributed to a cold. She becoming anxious, asked him to consult a physician and get a recipe."

The lady was asked to come to the office, and was persuaded to have an examination made, to confirm my diagnosis. When examined, the vulva presented a virgin condition, a thin hymen present, and the vaginal orifice so small as to hardly admit the small finger. In so doing the hymen was ruptured. As there was no vaginismus present, the disparity of the sizes of penis and vaginal orifice gave conclusive evidence that no penetration had occurred.

AIR IN PARTURITION.

Dr. P. McCahey, in an article in the *New England Med. Monthly*, says that the subject of the utilization of air in the function of parturition is an interesting and important study, and promises to furnish a means by which many accidents, hitherto unavoidable during labor, can be prevented.

He is aware that some will disbelieve that air exerts any direct influence in parturition, but when they consider that it is employed as a mechanical agent by many other organs of the body, they ought not to deny to the uterus the privilege of availing itself of the assistance of this powerful force.

Prior to the rupture of the membranes there is probably no air within the uterine cavity, except that which is held in solution in the amniotic liquor.

Immediately after the rupture of the membranes, however, air enters the uterus, and takes the place of the liquor amnii which has escaped. This displacement of fluid by air can be readily recognized by simple percussion of the uterine globe.

Percussion before escape of the amniotic liquor will give universal flatness or dullness. Percussion after their escape and throughout the second stage, will give diminished dullness over the fœtal parts, but distinct resonance at or near the fundus, and on the sides, *i. e.*, above and on each side of the child. Percussion after the expiration of the third stage, when the uterus has contracted into a hard ball, will give general dullness again. Percussion several hours later, when the uterus has become slighly relaxed and has ascended towards the umbilicus, will give resonance again.

These observations, he thinks, indicate that air is an important factor, not only during parturition in transmitting the muscular contractions with expansive force against the fœtus, and thus producing delivery, but that it is also a prime factor in causing the ascent of the uterus during pregnancy and for a brief period after delivery, and possibly in supporting it at all times. They also indicate that rupture of the perineum and rupture of the uterus, are not always due to direct muscular action, but are in great part the result of the sudden expansive force of the intra-uterine air when subjected to intense compression by the abdominal muscles, and confronted by a rigid perineum, or a firmly impacted head.

They also indicate, he thinks, that many hitherto unexplainable cases of still-births have been due to the subjection of the chil-

dren for too long a time to intense intra-uterine air pressure, and that they died as inevitably as adults will die who remain too long in compressed air, as in a caisson.

The facilitation of delivery, he believes, is therefore admirable in many cases, not alone for relieving the mother from pain and danger, but for the purpose of removing the child from a possible cause of serious disease, if not death, and delivering it healthy and vigorous, as well as alive.

GYNÆCOLOGY.

ELECTRICITY IN THE TREATMENT OF UTERINE FIBROIDS.

Chevrier (*Nouvellés Arch. d'Obstét. et de Gynéc.* October and November, 1891), after careful clinical research, has arrived at the following conclusions: The results following electricity in the treatment of uterine fibromyomata are inconstant and unsatisfactory; most of the patients, sooner or later, are obliged to undergo surgical operations for which they are not so well prepared as before the electric treatment. As a solvent of exudations, galvanism is absolutely ineffective. As an analgesic, it is very untrustworthy. As a hæmostatic, it gives fair results. Removal of the appendages does not give worse statistics than galvanism, and its results are better as to the rapidity of relief and duration of effects. In pedunculated tumors the continuous current is quite useless. Castration gives satisfactory results, but in these cases removal of the tumor is indicated, especially when pain and symptoms of pelvic pressure are well marked.—*Brit. Med. Jour.*

INCOMPLETE REMOVAL OF DISEASED OVARIES.

At a meeting of the Société de Chrirugie, Routier (*Ann. de Gynéc. et d' Obstét.*, November, 1891) said he objected on principle to Pozzi's method of conservative operations on the sclero-cystic ovaries. Conservative surgery, he holds, is irrational in cases of the kind, in oöphoro-salpingitis, and in cases of sclerosed ovaries where the tube is healthy. Pathological anatomy shows that in ovaries under these conditions all the ova tend to cystic degeneration. The stump left with part of the ovary on it is liable to to a return of disease, with the attendant sufferings for which the patient originally desired operation. At the same time, the patient is just as surely sentenced to sterility as though the whole of the appendages had been removed. The failures in many cases included in long series of operations for the entire removal of the appendages are in no small part due to the imperfect removal of the ovary; thus a piece of the ovarian tissue may be left on the distal side of the stump. It is equally unsatisfactory when the Fallopian tube is purposely left behind. In one instance Routier failed to cure a case of hæmorrhagic metritis with the curette. He removed the ovaries and left a healthy tube, all the trouble returned—a fact favoring Tait's theory on menstruation. At length Routier had to remove the uterus by the vagina. In two other cases, in women with metritis and retroflexion, where the curette had cured the flooding but not the pain, he fixed the uterus in position by hysteropexy, but left unremoved the almost healthy appendages on one side. A few months later he was compelled to perform vaginal hysterectomy. Pozzi replied that it was not by any means certain that a woman must necessarily remain sterile after conservative operations on the ovary of the kind which he recommended.—*Brit. Med. Jour.*

PÆDIATRICS.

NAPHTHALIN IN WHOOPING-COUGH.

Many remedies have been vaunted for the cure of whooping-cough, but with little satisfactory results in the majority of cases. A proposal to add napthalin to the long list of so-called cures has arisen in the following manner: Dr. Chavernac, of Aix, during a recent epidemic, seems to have allowed his son, who was 18 years of age, while suffering from the affection, to continue to attend school. One day the lecturer on science had burned some substance which gave off very strong fumes, which, though disliked by many of the boys, had the effect on him of immediately stopping a violent fit of coughing. As soon as the windows were opened, and the fumes passed away, the cough recommenced as violently as ever. His father, having discovered that the fuming substance was merely naphthalin, had about an ounce of it burned in the lad's bedroom, with the result that he breathed a great deal more easily, and only had one slight attack during the night. The next day, being at school, he had several attacks, but they were somewhat less severe than they had previously been. The next night the drug was again burnt in the bedroom, and this second dose entirely cured both the cough and the expectoration, which latter had been rather profuse. The father was then attacked, and in three days cured himself by the same treatment. He

subsequently tried it with several of his patients with marked success, and with the concurrence of a friend, who was medical officer to a convent school where the epidemic was raging, he tried it on thirty affected children. After the naphthalin had been burnt two successive nights in their dormitory, they were all cured. Two of the nuns, however, found the fumes very irritating, and, on these ladies being examined, it was discovered that they were both suffering—quite unknown to themselves—from incipient phthisis. From this, and from further observations, Dr. Chavernac has come to the conclusion that naphthalin is contra-indicated in phthisical persons, and that it may sometimes serve to reveal the existence of totally unsuspected tubercle. It may be remarked that the so-called albocarbon used freqently for enhancing the lighting power of gas, is somewhat crude naphthalin. The method employed by Dr. Chavernac is to place about three-quarters of an ounce in a metal dish surrounded by hot coals. It soon melts, and before long fills the room with white fumes, which he considers by no means unpleasant. The old custom of taking children to gas works for whooping-cough has generally thought to depend on the curative effect of gas tar; but from the above it would appear that the naphthalin which crystalizes out in the retorts and pipes is, perhaps, really to be more credited with efficacy than the tar.—*Lancet.*

TREATMENT OF CONVULSIONS IN CHILDREN.

In the treatment of convulsions Decroizilles (*L'Union Médicale*) recommends that the child be taken at once to a well-ventilated room, and that the clothing be removed in order to discover any points of irritation to the skin. A lukewarm bath, either with or without the addition of mustard, should next be given. The head should be kept cool by means of cold applications, or even by a stream of cold water kept constantly running upon the fontanelles. In Germany and Switzerland convulsions produced by hyperpyrexia are treated by plunging the child at once into a cold bath. As the irritation may be due to the digestive tract the fauces should be titillated or an emetic administered. If the stomach be tense it is advisable to use a purgative, 10 to 20 cgrm. (1½ to 3 grs.) of calomel, or 5 to 15 grammes (lxxx to ℥ss) of castor oil, or 8 to 16 grammes (f℥ij to f℥ss) of manna suspended in milk. If the child has given passage to a worm an immediate vermifuge should be administered. If there be cerebral hyperæmia, the application of several leeches behind the ears or to the thighs or the tibio-tarsal region is recommended. In vigorous children venesection, either from the arm or from the saphenous vein, can at times be employed. Warm cataplasms, prepared with mustard, can be applied to the lower limbs. The carotid arteries, following the precautions laid down by Trousseau, may be compressed with care. Inhalations of chloroform are capable of giving good results, but they are only transient, and their repetition is not without danger. When the duration of the convulsion is prolonged, 5 to 40 cgrms. (¾ to 6 grs.) of oxide of zinc, with equal parts of henbane, may be given. The bromides, associated with chloral, give especially good results. The dose of the bromide should be ½ to 1 gramme (7½ to 15 grs.) in very young children, 2 to 4 grammes (℥ss to ℥i) in older children, and 4 to 6 grammes (℥i to ℥iss) in those approaching convalescence. Chloral should be administered in 5 cgrms. (gr. ¾) in the newborn baby, 15 to 20 cgrms. (2¼ to 3 grs.) in the nursing baby, 20 to 30 cgrms. (3 to 4½ grs.) below two years, and 40 to 80 cgrms. (6 to 12 grs.) in children from 7 to 13. The administration of chloral should be promptly suspended and renewed if there be any necessity. After the attack the child should have complete rest; and tonics, with the prolonged use of the bromides, cold affusions to the head, with baths and strict hygienic alimentation, should be ordered. It is wise, from time to time, to advise that the child be given small doses of calomel, valerian and oxide of zinc.

INHALATIONS OF OZONE IN THE TREATMENT OF WHOOPING-COUGH.

Dr. Hellet sets forth, in the *Revue International d'Electrotherapie*, the results which he obtained in the treatment of whooping-cough with ozone, as follows:

Ozone produced by electricity has never given rise to unpleasant effects in our hands. We have ascertained that ozone is a powerful reconstructive, an incomparable modifier of the blood, since it is necessary to breathe strongly ozonized air for only a quarter of an hour in order to increase, in certain cases, the proportion of oxyhœmoglobin one or two per cent. when it is already 14 per cent.

Though opinions may have differed concerning the beneficial therapeutic effects of ozone, there has not been any dispute about its disinfecting and antimiasmatic actions.

Numerous experiments have shown that it acts powerfully upon germs and ferments, that it arrests their development and even destroys them. In view of this fact, and remembering also, that ozone is a powerful reconstructive, I do not hesitate to prescribe inhalations of ozone to little children suffering from whooping-cough, thinking that this disease, which is of microbic origin, would be favorably modified.

Up to the present time only four cases have been treated: a girl of six years, another of five, another of two, and a boy of fifteen months. These children inhaled ozone every day for fifteen minutes. In every case the number of paroxysms was carefully noted.

In all of these cases the course of the disease was favorably modified. The number of paroxysms diminished, and their general condition rapidly improved, which is a very important consideration; they became cheerful, and the appetite was restored.

The parents always noted that the children became more playful after the inhalations of ozone; their paroxysms became less violent and less exhausting.

The duration of the disease seems to have been shortened.—*La Medecine Moderne.*

SOME REMARKS ON THE TREATMENT OF DIPHTHERIA.

Dr. Szuman, of Thorn, remarks that all internal remedies applied against diphtheria may divided into three categories: (1) Remedies dissolving fibrinous membranes; (2) antiseptics, and (3) specifics for diphtheria. In the light of the progress of science, which has proven that the membranes are not the real localization of the disease, but the deeper-lying tissue, and very often the whole organism, the value of the remedies of the first category become very doubtful. A somewhat greater value is attributed to antiseptic drugs, their value being seen principally in the preventive treatment. Of the drugs in the third category, it can only be said that none deserves the name of a specific. Later, acids began to be employed; their action, however, is not as yet sufficiently known.

The method that Dr. Szuman employed is founded upon the application of three acids, namely, upon the internal administration of acetic acid, inhalations of carbolic acid, and gargling the throat with a solution of boric acid. The result of this treatment, in comparison with those employed up to the present time, is satisfactory, because out of thirty cases treated by this method all recovered. Though, indeed, in two cases the diphtheritic process extended into the larynx, nevertheless recovery ensued—in the first after inhalations of acetate of aluminum, together with internal treatment, and in the second after tracheotomy.

Reflecting upon the mode of action of acids on the human organism, the author came to the conclusion that we may, perhaps, have to do here with local action, the observations showing that acetic acid can pass through the unbroken skin; and Brun's experiments proving its antiseptic properties, even when much diluted, confirms this opinion. He does not exclude the possibility that the acid reaction in the oral cavity arrests the diphtheritic process. The employment of alkalies, viz., lime water, acting on the development of putrefaction, as well as all mechanical methods, he regards as dangerous, and believes that the advantages of his method consist in constantly keeping the throat and oral cavity in a state of disinfection and acidity, which arrest the putrefaction of membranes.

CITY DUST.

Dust, like the poor, we have always with us, nor has Hygeia with her newest brooms yet succeeded in banishing it. Yet there is abundant evidence to show that a dusty street contains more lurking potentialities of mischief than a jungle peopled with the hungriest wild beasts. To the researches of Miquel and others can now be added the results of an elaborate investigation by Dr. Luigi Manfredi of the composition of the dust of the streets of Naples. The number of microbes of all kinds found in it amounted on the average to 761,521,000 per gramme. Remarkable differences in the proportion of micro-organisms were, however, observed in the dust from different quarters of the city. Thus, in the streets least exposed to contamination, that is to say, where there was the least traffic and where the hygienic conditions were most satisfactory, the average number of microbes in the dust was only 10,000,000 per gramme. On the other hand, in the busiest thoroughfares, the average rose to 1,000,000,000, and in some of the dirtiest streets to the enormous figure of 5,000,000,000 per gramme. In this "endless ocean" of infinitesimal life, there was a large number of pathogenic organisms, and the unhealthiness of the street or quarter was directly proportional to the number of microbes in the dust. Dr. Manfredi carefully tested the infective power of the dust, and obtained positive results in 73 per cent. of his experiments. Of forty-two

cases in which he communicated disease to guinea-pigs by inoculating them with Neapolitan dust, he found the microbe of pus in eight, the bacillus of malignant œdema in four, the bacillus of tetanus in two, the bacillus of tuberculosis in three, not to mention several other microscopic *ferœ naturæ* possessing the power of inducing fatal septicæmia in the unfortunate guinea-pigs on which they were tried. The moral pointed by these discouraging facts is that our Ædiles should take the Dutch housewife for their example, and wage relentless war against dust and dirt of every kind.—*Brit. Med. Jour.*

SHORTENING OF BEIDERT'S METHOD FOR FINDING TUBERCULAR BACILLI IN THE SPUTUM.

Dr. Kronig has applied the centrifuge to the examination of the sputum, with the result that a considerable number of tubercular bacilli were found in a case where the ordinary method had failed to reveal them. The sputum was diluted with a solution of caustic soda, and on the application of centrifugal force for five minutes, a somewhat compact sediment was separated, which gave the above result on examination. By Beidert's method the sputum so diluted has to stand for two or three days to allow of the precipitation of the bacilli. Professor Litten has explained the application of Stenbeck's centrifuge to clinical medicine.—*Boston Med. Sur. Jour.*

FISSURES OF THE ANUS IN CHILDREN.

Dr. Bruun (*Hospitals-Tidende*, R. 3, Bd. 8, S. 1089) finds the use of lime water as an addition to milk a frequent cause of constipation and consequent fissures of the anus in children. Any cause which produces diarrhœa, with following constipation, will cause it. Constipation, proctitis, and severe pains on defecation are the results of a fissure. Hernia and masturbation are possible consequences. The condition may be long-lasting, although it is easily discovered when attention is called to it. He treats it by regulating the diet, cleanliness, irrigation of the rectum, and dilatation of the sphincter ani, which is easily done.

HYGIENE.

WHAT IS EFFICIENT VACCINATION?

That there is a difference of opinion, both in and out of the profession, as to what constitutes efficient vaccination is evident from the frequency with which the question is put by mothers, "In how many places do you vaccinate?" My invariable reply is, "In four places." This often provokes an earnest appeal only to vaccinate in two, and sometimes even in one place, and this request is followed up by the remark, "Dr. So-and-So only puts two on," and I have heard medical gentlemen credited with vaccinating only in one place, and with avowing that one was enough.

After a little reasoning, I generally gain my point, and four vesicles is the result. If the mother continues obstinate, I give in to three, but in a measure I still gain my point by trying for, and generally securing three extra large vesicles on the eighth day.

Below three I never go, and if the parents —for the father is sometimes appealed to— still hold out, then I decline to vaccinate the child, and retire from the case.

There ought not to be such a difference of opinion amongst medical men as to how many vesicles give evidence of protection from small-pox; and if we were unanimous, mothers would soon be willing and even wishful for their children to be efficiently vaccinated. Public vaccinators are enjoined, in the instructions they receive from the Local Government Board, to secure, if possible, four good vesicles on the eighth day.

A few years ago, when application was made to the Local Government for calf lymph, with the lymph came a leaflet of instructions, which advised, amongst other things, that the "lymph be rubbed into each of four or five places" in the child's arm. These instructions are now discontinued.

During the epidemic of small-pox in Leeds in 1870, my colleague, Dr. Fredk. Hall, and I, having charge of the small-pox hospital, tabulated the evidences of vaccination of each case on admission. We found that those cases who showed four vaccination cicatrices on the arm were few in number, and had the disease in a mild form. Those with only three or two marks on the arm had the disease more severely, and were in the hospital a longer period, and of the unvaccinated cases the majority died. This was conclusive evidence that at least four vesicles should, if possible, be obtained, and thus secure what is generally considered efficient vaccination.

Imperfectly vaccinated cases, when they fall victims to the small-pox, are just those who, being registered as successfully vaccinated, throw discredit on the system, and generally help to keep up the disease in an endemic form.

As a remedy I would venture to make two suggestions: (1) That a short paragraph be inserted in the ordinary vaccination certificate, informing the parents that the child should be vaccinated in at least four places, and that this, and this only, constitutes efficient vaccination. (2) That a small space be left, say just above the date and signature on the third page of the certificate, in which space the vaccinator be required to note in figures the number of places in which the lymph has been inserted, and the number which have "taken" on the eighth day, and that these figures be duly entered by the registrar in his book. Thus, in after years, when small-pox breaks out, the names of the victims can be turned to in the register, and the number of vesicles noted, which had originally been obtained and certified as successful vaccination.

In this way valuable evidence will be obtained as to what constitutes efficient vaccination, and the more strictly carrying out the requirements of the law will be facilitated. I am, etc.—Henry C. Libbey, in *British Medical Journal.*

BENZINE AS A PREVENTIVE OF TRICHINOSIS.

Dr. Putter, jun., of Stralsund, reports in the *Deutsche Medicinische Wochenschrift* on the favorable effect of benzine after the consumption of pork full of trichinæ. A pig had just been killed, and some hours after twenty-seven people had eaten of the meat the inspector informed the owner that the animal had been suffering from trichinosis. All the twenty-seven people, adults and children from fourteen to seventeen years, had boiled pork for dinner; the wife of the owner and four other women, in making sausages, had repeatedly tasted the raw material. Dr. Putter was informed of the mishap the same evening, and prescribed 270 gelatine capsules, each to contain seven and a half grains of benzine; each person to take five capsules the next morning before breakfast, and an hour later a large teaspoonful of pulv. rhei. and pulv. glycerrhizæ co. in equal parts—the children, of course, less in proportion. The same dose was to be repeated in the afternoon, and the purgative only the next day. The benzine was well borne by all the patients, a few only complaining of malaise aud eructations, but none of them vomited. Eight months later all the twenty-seven people were still perfectly healthy, as were the women who had tasted the raw sausages. Dr. Putter is so convinced that his treatment alone prevented the people from being attacked by trichinosis that he recommends it warmly in all similar cases.—*Lancet.*

MEDICAL CHEMISTRY.

ACETANILIDE FOR THE PRESERVATION OF HYPODERMIC SOLUTIONS.

Thomas J. Keenan writes in the *Amer. Drug.* of the various chemical bodies known to exert an inhibitory action on the development of the fermentative and fungoid growths which occur in simple solutions of the alkaloids prepared for hypodermic use, and in solutions of organic chemicals generally, acetanilide, from the consideration of its non-irritating properties and its efficiency in weak solution, in his opinion easily takes first place.

Glycerin, alcohol, salicylic acid, boric acid, chloroform, and a host of others, chiefly derivatives of the aromatic hydrocarbon series, have been at different times strongly recommended for their individual properties, and used with favorable results; but experience has demonstrated that all have their objectionable features.

Glycerine is seldom used on account of its slightly irritating properties and the increase of density which follow its addition.

Alcohol is irritating and liable to cause precipitation.

The chief objection to the use of salicylic acid, apart from its readiness to react with other chemicals, and one which may be overcome at the discretion of the pharmacist, is the strength in which it is directed to be used.

This is stated by the compilers of the Addendum to the British Pharmacopœia, and other official bodies, to be a saturated solution representing about one grain in one fluid ounce, thus affording a concentration considerably in excess of the amount actually required; solutions prepared wlth it in the proportion of one-eighth grain in one fluid-ounce keeping equally as well as the stronger ones, besides being less liable to cause the precipitation which sometimes takes place in concentrated solutions of morphine or similar bodies of long standing.

Boric acid is only suitable for a limited application, being, however, especially well

fitted for the preservation of cocaine solution when the latter is intended for local application.

Chloroform, in the form of Aqua chloroformi (N. F.), is generally considered the most useful of any of the preservatives yet proposed, and is, perhaps, more widely employed than any other in the list here given. It is non-irritating and convenient of use, besides being free from the danger of reacting with the substance it may be added to. It is, however, less reliable, in his opinion, from its evanescent nature, than either salicylic acid or acetanilide, particularly when evaporation is assisted by the frequent removal of the stopper in extensive dispensing.

IMPROVED PROCESS FOR CONDENSED MILK.

A Russian chemist uses a centrifugal machine for separating the cream and skimmed milk. The casein is then precipitated from the latter, and condensed at a low temperature in a vacuum pan having a sight of colored glass which admits yellow or red light, it having been found that the more refrangible rays have a deleterious action on the miscibility with water of the condensed product. The acidity of the milk is not allowed to exceed a limit of 5.5 (Soxhlet-Henkel), and to this end a definite quantity of caustic or carbonated alkalis or alkaline earths are added to the milk. The condensed milk is mixed with the cream and milk sugar.

DETECTION OF FATS MIXED WITH VASELINE.

Caustic alkalies are without action on the normal constituents of vaseline in the process to be described, whilst they combine in definite proportions with the fats to form soaps. Experiment has determined that 10 gm. of these fatty compounds absorb 1.635 gm. of potassium oxide, K_2O, and the calculations are based on this. A standard alkali solution is prepared by dissolving about 20 gm of potash in 100 cc, of 90 per cent. alcohol. This is standardized by means of standard sulphuric acid. A neutral alcohol is prepared by dissolving one cc. of phenolphthalein in 500 cc. of 90 per cent. alcohol, then alkali is stirred in drop by drop until a very slight rose tint is produced. Ten gm. of the vaseline to be tested are placed in a 200 cc. porcelain basin, ten cc. of standard alkali added, the basin being kept on a water bath during the whole process; 50 cc. of neutral alcohol are now added, the solution heated nearly to boiling, and the mixture stirred for eight minutes, when the saponification will be complete, and normal sulphuric acid added drop by drop until *all color* has disappeared. This point is very important. If too long a time has been taken it may be necessry to add a fresh portion of neutral alcohol to replace the loss by evaporation. The amount of sulphuric acid run in, subtracted from that required to saturate ten cc. of alkali solution. multiplied by 0.0047 gives the quantity of potash absorbed by the fats in ten gm. of vaseline, and this number divided by 0.0163 gives the percentage of fats in the vaseline.—Mr. Vizern and C. Nicolas in *Journ. de Pharm.*, after *J. Chem. Soc.*

REMEDY FOR BUMPING.

E. Pieszezek, in the *Chemische Zietung*, gives a description of a simple device made use of by him for the prevention of the phenomenon known as "bumping" in boiling liquids. It consists in placing a glass tube about 5 to 8 ccm, in length, and 5 to 10 minims in width (the exact dimensions depending upon the bulk of the liquid to be boiled), and closed at the upper end, resting upon the side of the flask or other vessel to be heated, so that it stands nearly vertical, with its open, sharp-edged end pointing downwards. Boiling goes on quietly when once started, the bubbles making their appearance at the lower end of the tube. On cooling, the liquid rises in the tube, which must therefore be raised and allowed to again become full of air before beginning the boiling again. The device is said to be efficient even for liquids containing heavy precipitates such as barium sulphate and lead sulphate, and is also recommended for the Reichart-Vollny process.

THE ESTIMATION OF MILK SUGAR IN MILK.

The main difficulty in the determination, as ordinarily carried out, is in obtaining a filtrate sufficiently clear for titration. As prepared by the usual methods, it is opalescent or even quite turbid from the fat which passes through the filter.

It has been found, by making use of the well-known property of aluminium hydrate, to drag down precipitates, and by following the recommendations of Radliscu (*Mittheil. d. pharm. Inst.*, Erlangen, iii., 93) regarding the amound of acid, intensity and duration of heating, all of which are of great importance in the rapidity and completeness of the curdling, that a clear filtrate is readily obtained.

The method is as follows: 25 cc. of the milk are mixed with 15 cc. of "milk of alumina," and 0.5 cc. of 25 per cent. acetic acid added, the mixture stirred and heated five to seven minutes in a water bath the temperature of which is 85° C.; 100 cc. of water are now added, and the mixture is heated in boiling water for ten minutes, with frequent stirring. It is thoroughly cooled under the tap, allowed to settle, and decanted through a plaited filter (Schleicher & Schüll, No. 597) into the 500 cc. graduated flask, being careful to bring as little precipitate upon the filter as possible. The operations of boiling and filtering are repeated three times, and the filtrates made up to 500 cc. It is then ready for titration by Fehling's solution in the usual way.

The "milk of alumina" is prepared by precipitating at the boiling temperature 125 gm. ammonia alum with ammonium hydrate, washing the precipitate by decantation, and making it up to 1 L.

The method has been in use by the students at the Massachusetts Institute of Technology for a year, and given very satisfactory results.—Aug. H. Gill, in *Journ. Anal. and App. Chem.*

NEWS AND MISCELLANY.

A Chinese translation by Dr. Hunter of the British Pharmacopœia has been recently published.

Lysol has been found to deodorize a case of moist gangrene, in which a solution of permanganate of potash, and creolin had failed.

A successful case of bone-grafting is reported from Allahabad, a solution of continuity in the anterior layer of the frontal sinus having been induced to take on osseous repair by sprinkling the surface with "small fragments" of the hip-bone of a newly killed dog.—*Medical Press.*

MATTHEWS DUNCAN MEMORIAL.

At the last meeting of the Aberdeen University Court a letter was submitted from Professors Alexr. Ogston and R. W. Reid, formally handing over to the Court a bust of the late Dr. Matthews Duncan, to be placed in the Medical School, and a check for £140, to be invested to provide a gold medal to be known as the "Matthews Duncan Gold Medal in Obstetrics.—*Brit. Med. Jour.*

THERE'S THE RUB.

To vaccinate or not? That is the question,
Whether 'tis be'er for man to suffer
The painful pangs and lasting marks of small-pox,
Or to bare arms before the surgeon's lancet,
And, by being vaccinated, end them? Yes,
To feel the tiny point, and say we end
The chance of many a thousand scars,
That flesh is heir to, 'tis a communication
Devoutly to be wished. Ah! soft you now,
The vaccination! Sir, upon your rounds,
Be my poor arms remembered.

—*Puck.*

RUBBER FOOT FEVER.

If a man has a corn, says the *India Rubber World*, it can be removed, but if he is suffering from rubber foot fever, no chiropodist can help him, and the only thing to prescribe is liberal bathing of the feet and removal of the cause. Rubbers should only be worn to keep wet out, and they should be removed the moment the wearer gets indoors. Failure to note this gives a man wet feet in a far worse sense than if he waded through mud ankle deep. It was the trouble resulting from forcing the perspiration to soak the stockings and keep the feet perpetually damp that drove rubber-soled boots out of the market. Even loose rubbers are a source of danger, and the cause of more serious colds than they avert.

THE EFFECT OF FOG ON ACTINIC LIGHT.

A committee of the Field Naturalists Society have ascertained the composition and character of the air in four stations in Manchester and two in Salford. The Committee find that a very marked increase has taken place, both in sulphurous acid and organic matter, especially during the past month. Speaking generally, the district of Ancoats and the centre of the city show the greatest amount of pollution. The amount of light (chiefly actinic) was measured for each day; the difference between town and country became more and more pronounced as the winter months were reached. Fog cut off the actinic light almost completely, the record in the country (free from fog) being for the same day ten to twenty times that in Manchester. The general falling off of light as the season advances was most striking, the amount in October, taking similar days, being little more than one-third that measured for August.—*Brit. Med. Jour.*

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.
A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN
In Doses of from 10 to 20 Grains,
AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF
Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,
caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the *Proportion of Oil* it contains.

3d—In mode of manipulation and thorough incorporation, rendering it *Permanent* and *Palatable,* and of proper consistence, *about that of Rich Cream.*

4th—*In Size of Bottles,* containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

CLINICAL LECTURE.

MULTIPLE NEURITIS.

By PROF. A. FRAENKEL, M. D.
BERLIN, GERMANY.

Gentlemen :—The disease which I will take the pleasure of showing you a few cases of to-day, was recently spoken about in the Society for Internal Medicine by Dr. Senator, and called forth a most animated discussion. Dr. Senator showed two specimens which gave evidence of an especially aggravated affection of the muscles. The same was manifest in a decided hyperæmia of the vessels running between the single muscle bundles, a collection of circular cells around these and the appearace of seed-like growths resulting from "pressure-atrophy" of the muscular fibres. Especially in the second preparation demonstrated by Dr. Senator, the primary symptoms had been pains in the muscles, while evidences of a morbid condition of the nerves, such as pain or pressure or anæsthesia were absent and only appeared at a later stage of the disease. Dr. Senator, therefore, expressed it as his opinion that in a certain class of cases of multiple neuritis, the disease finds its origin in an affection of the muscles, and starts with being confined to the muscles, and that it is only at a later step the nerves are attacked. He is also the opinion that apart from the acute or subacute polyneuritis, there exists also an acute infectious polymyositis.

If we stop a moment to glance at the overwhelming amount of literature which has been published during the past few years on the subject of multiple neuritis, we will find that the increase of knowledge gained is due, primarily, to the greatly increased symptomatic complex, and, secondarily, to our knowledge of the patholo-anatomical change occurring in the disease. The well-known work of Leyden, and later of Duchenne, has enabled us to class those affections formerly termed as acute and sub-acute spinal atrophy and acute and sub-acute anterior spinal paralysis, under the head of mutiple neuritis, and so most recently the effort has and is being made to pay special attention to changes in the central nervous system, and especially in the spinal cord, in cases of multiple neuritis. Leyden in his work, and after him Oppenheim, have not infrequently recorded changes in the gray substance of the cord, which consist in certain alterations in the cells. In some cases hyperæmia of the gray substance and also isolated points of myelitis were found.

All the same it does not seem probable that these changes in the cord were the starting point for the morbid process in the periperal nerves. Of special interest are certain changes in the white substance of the cord which have been frequently observed by recent investigators and to which, lately, more importance has been placed.

The last writer in this field, whose work I have in my hands, is Pal. He claims that these changes of the substance of the cord constitute the principal factor through which we must seek to determine the pathogenesis of multiple neuritis. He cites the history of eight cases in his monograph upon the subject in four of which he obtained *post-mortem* examinations, and in all forms of these he found distinct changes in the substance of the spinal cord. The changes consisted in one case in hyperæmia of the gray substance with capillary hæmorrhages in the posterior and anterior bones; in a second case they consisted in a partial degeneration; in a third case there were also extensive degenerations of the gray substance, both in the cervical and lumbar regions. Pal expresses the opinion that the toxic element in multiple neuritis, may affect different points in the nervous system in succession or simultaneously.

It is interesting to note, in this connection, that the degeneration of the cord is not a general or progressive one, but that it occurs at separate points, often distant from one another.

If such changes are of frequent occurrence in this disease, the symptomatology becomes at once much more complex.

It will be seen that we can have a complication of tabes and multiple neuritis—or a neuro-tabes peripherica. I am reminded of the works of Dejerine and others who have demonstrated a morbid process of the sensory as well as the motor nerves in cases of tabes neuritis, so that in the course of tabes a motor paralysis resulting in subsequent atrophy can occur.

Clinically also is it sometimes difficult for us to determine whether we are dealing with neuritis or tabes. In this respect, I do not refer to the similarity of the more gross symptoms, such as pain, loss of the knee-jerk, paralysis of the optic muscles, but to others, such as bladder troubles, gastric irritability, girdling pains, etc.

I had a case not long since in this clinic, in which there had been gastric trouble for years, but which after the manifestation of the girdling pains about the waist lead to a diagnosis of tabes. Later, however, Dr. Remak was able to detect degenerative atrophy in the forearm and also in the lower extremity, so that the final diagnosis of multiple neuritis was reached. We come now to a demonstration of the cases. I will begin with those cases that ended fatally, the results of these autopsies I have here.

Case 1. The patient from whom I obtained this microscopical section, is interesting to us on account of peculiar changes, which have been recently observed in other cases of multiple neuritis, to which Korsakoff first called attention. These are seen most frequently in cases of alcoholic neuritis, and especially in the infectious forms of neuritis. They are also observed in neuritis consecutive to ileo-typhus, and in those forms of neuritis in which toxic substances are taken up in the organism, as after abortion, etc.

This complication is remarkable for the following symptoms:

In one series of cases there will be a manifest weakness of the psychical sphere; the patients are sleepless, easily excited and put out of sorts. In a second series of cases there is a want of collectiveness and consistency regarding time and place, and a sense of confusion. In a third series, the patients will show great forgetfulness, they can under certain circumstances answer promptly and coherently, and then again will show absolute ignorance of most recent occurrences.

Korsakoff states that this complication so completely masks the symptomalogical picture of multiple neuritis as to render a correct diagnosis most difficult. Besides these symptoms the patient is usually greatly emaciated, has an uneven, quick pulse, and suffers from persistent vomiting. All these symptoms were present in the case I have just demonstrated.

Case 2. The patient was 50 years of age, who had the year previously been admitted, on November 26th, to the City Hospital of Berlin, located at Urban. The disease had begun on about the middle of August with pains in the limbs; eight days later he could not walk, and six weeks before his admission to the hospital physical disturbances had begun to manifest themselves—he became confused, and there was an inability to keep his mind fixed upon any certain subject.

Upon examination a high degree of amnesia was observed, he had forgotten things which occurred but recently, he did not know where he was, and, coupled with these psychic disturbances were all the symptoms of a well-developed case of multiple neuritis. According to his wife, the patient was a pretty hard drinker, and in former years there seems to have been some syphilitic affection. There was a high degree of weakness in the lower extremities, the knee could be only slightly bent, and there was a decided diminution of the sensibility of the limbs. The reflexes were absent, with the exception of a very slight reflexes of the sole of the foot; knee-jerk was absent, the nerve roots were very painful upon pressure.

In the upper extremities there was a marked atrophy of the extensors of the forearm and of the small muscles of the hand. The weakness of the limbs—especially of the upper extremities—increased materially. The patient became weaker and weaker, and soon went into a condition of violent delirium and gradually sank under manifestations of profound prostration. On the last day of his life his pulse was 120, respiration 48, and temperature 38.70° C.

The autopsy, apart from a flabby heart, showed but few microscopical changes. Even the nerves, as far as the naked eye was concerned, showed no morbid changes. The following nerves were examined microscopically: the crural, perineal, ulnar and radial, and show from their roots to their endings a high degree of degeneration—seen principally in a degenerative loss of the white substance of Schwann. The muscular substance was but little changed. The cord was intact. The brain showed no marked pathological changes.

Case 3. This case is that of boy, 14 years old, who came to the hospital on August 12,

last year. As you see, in this patient there has been a gradual but unusual degree of polysarcia, not only of the extremities but of the trunk, so that any one of you who now see him for the first time, might well imagine, on account of the general condition of the muscular tissue, that we are dealing with a case of Erb's progressive muscular dystrophia. At the time of his admission to the hospital the maximum circumference of the calf of the leg was 24½ centimetres, and since being here there has been an increase of 10 centimetres. The circumference of the thigh has also increased 5 centimetres. The patient cannot ascend a step without assistance. There is a comparatively well-marked lordosis in the region of the lumbar vertebræ, similarly as in cases of dystrophia of the muscles. When seated in a chair and asked to rise without making use of his left or sound arm, he is unable to do so on account of the extreme paretic condition of the muscles of the back—in this peculiarity we see a similarity to pseudohypertrophy of the muscles. You see also the stone-like appearance of the calf as in case of pseudohypertrophy of the muscles. But we are not dealing with this disease in this case, which is one of multiple neuritis.

The right arm is entirely paralyzed, the only movement possible being a weak contraction of the fourth and fifth fingers, while the muscular atrophy of the arms is greatly hidden by the large amount of fat; still that of the deltoids is plainly to be seen, especially when the arms are held horizontally. The gait of the patient is very peculiar. In consequence of the great weakness of the extensors and flexors of the foot he does not walk normally, but rotates his legs outwardly, and in bringing each leg forward describes half a circle, and walks with his feet far apart. This peculiar gait is associated not only with a weakness of the muscles of the feet but also with a weakness of the psoas muscles.

The patient says that the disease was originally caused by working in the wet. He was compelled to stand for a long time in water, and felt ill immediately afterwards, and was compelled to go to bed. In a few days he felt a tingling sensation in his right arm, and two days later was unable to move it. After lying in bed for twelve days, he endeavored to get up, but fell to the floor immediately. At the hospital we found a complete paralysis of the right arm, and a weakness of the left, especially in the shoulder, and also a decided diminution of the motor power of both the lower extremities. In the left upper extremity, the elbow could be moved pretty freely, and the hand and fingers could be stretched and bent, but supination was most difficult. Triceps reflex was entirely absent from the right arm, and only very slightly present in the left. Patellar reflexes absent in both limbs, also foot reflex absent. Both flexion and extension of both feet almost entirely impossible; in the left leg the knee and hip-joint could only be slightly bent.

What was most striking in the case was the intense painfulness of the muscles, and also of nearly all the nerve trunks, so much so that the patient would cry aloud if touched even most gently Even the skin was exquisitely sensitive. While the tactile sense was normal, there were also intense spontaneous pains in the muscles, especially when the fingers were moved, also paræsthesia in the form of tingling and creeping sensations in the lower extremities. The pupils were equal and reacted normally to the light. Temperature normal. Pulse fluctuates between 68 and 76.

The patient is being treated with faradism in connection with a constitutional treatment. When admitted to the hospital he weighed 29.5 kilogrammes, and now, after a year's sojourn here, weighs 52 kg., his gain being 22.5 kg. This enormous polysarcia, caused by the long confinement in bed, coupled with a very rich diet, completely hides the atrophy of the muscles. The prognosis of a restoration of the paralyzed parts is poor. The boy is, however, learning to write with his left hand.

Case 4. This case shows better results in the amelioration of the paralysis. The patient is a driver, 29 years old, who had a most severe attack of tubercular neuritis. The patient was twice in this institution, first in October of 1890, during which time he was treated for pulmonary catarrh. Two months after his discharge (which was in December), he returned again, but this time with a totally different condition: Both upper extremities were entirely paralyzed, and the lower extremities paretic in a high degree, so that they could hardly be lifted from the bed. There was a slight paresis of the facial muscles, hoarseness in consequence of a paralysis of the left vocal cord. Further, great painfulness of the muscles, as well as painfulness of the nerve trunks. Patellar reflex but very slight. The patient has a good deal of spontaneous pain, and could not sit up. Under a careful nutritive therapy these symptoms gradually abated, although the phthisis from which the patient was also suffering in no way improved. As the paralysis lessened he had frequent attacks of hæmoptysis. There now only remains a weakness of

the hands, especially of the extensors. The physical condition of the patient has also improved.

COLLES FRACTURE. — BURSITIS OF WRIST. — RICE-GRAIN BODIES. — SCIATIC NERVE-STRETCHING.

By ROSWELL PARK, M. D.
BUFFALO, N. Y.

Gentlemen: I have brought this case before you in order to illustrate some of the untoward results of fractures. This woman is 52 years old and she tells me that ten weeks ago she fell and hurt her wrist, which swelled somewhat during the night. The next morning she consulted a physician who diagnosed a fracture of the fore-arm, put on a long anterior splint, and told her that it would "come out all right." Ordinarily fractures in which the lower end of the ulna or radius is involved, result from falling upon the palm of the hand with the arm and hand extended to save one's self. In this particular instance, however, the fall was upon the back of the wrist and the lower end of the ulna while the hand was flexed and pronated.

As I hold her hands up symmetrically, you notice a marked difference in the contour of the two wrists. I cannot rotate the injured hand outward as much as I can the other. There is not much alteration in the appearance of the radial side of the wrist, but from a palpable thickening of the lower end of the radius, I infer that the patient had at the time a Colles fracture. As my predecessor in this school, Dr. E. M. Moore, so earnestly and so eloquently taught, the most important lesion of a Colles' fracture is often the complication of displacement or even fracture of the ulna. Occasionally the internal lateral ligament is perforated by the styloid process of the ulna and this process may even be broken off by the violence. Occasionally we have a compound dislocation of the ulna, compound in the sense that the styloid process, after perforating the internal lateral ligament, perforates the skin also. Usually when there is trouble with the ulna as well as the radius, the damage is rather on the dorsal aspect of the wrist than in front. Whether there was fracture of the ulna in this case I do not know, but there is no nonunion at present. I take it that, instead of being fractured, the ulna was dislocated forward, and whether the dislocation was reduced at the same time that the fracture of the radius was dressed I do not know, but now I find a condition of subluxation of the lower end of the ulna in combination with a good deal of thickening and callus formation about the lower end of the radius and sufficient binding of the bones to prevent much rotation of the forearm. Flexion of the fingers and movement of the thumb are much interfered with by adhesions of the tendons within the tendon-sheaths. These adhesions have followed a tendo-vaginitis at the point where the sheaths pass in front of or behind the parts most injured.

There is enough in this case for a whole morning's lecture. Unfortunately I have not time for that, but I show you the case hastily, first, because it illustrates the result of some of the complications of Colles fracture, secondly, as a text for further discourse on the proper treatment of such cases, and thirdly, that we may consider what can be done at present for the relief of the patient.

Our worst results after Colles fracture are encountered in patients of advanced age rather than in early life, and persons of the age and build of this woman are, unfortunately, predisposed to the formation of fibrinous exudates which are thrown out easily and absorbed with difficulty. Questioning her with regard to rheumatism, I find no history of anything more than considerable pain in the left shoulder and she has never had any acute attack. A person with the rheumatic diathesis, who has had in the past an acute attack of the disease, is much more liable to have involvement of the tendon sheaths following an injury of this kind than are persons without the diathesis.

What can be done to relieve the existing state of affairs? If the patient were quite young and vigorous I should advise anæsthesia and forcible flexion and extension, and perhaps efforts to restore the ulna to its place and hold it there. But ten weeks have now elapsed since the accident and the patient through in ordinary health, is neither young nor vigorous, and there is not enough prospect of success with that form of treatment to make me feel like urging it upon her. A more serious and more radical but more hopeful operative procedure would be to resect the lower end of the ulna so as to render greater movements of the wrist possible. The patient hesitates about undergoing any operation, however, and I have advised her therefore to wait a while, to soak the hand and fore-arm twice daily in water as hot as she can bear it, and to follow this with various mainpulations of the fingers and wrist for half an hour. The patient says she has rubbed the hand, but on questioning her about the

movements she has used, it becomes evident that her manipulation has been of a very superficial and unsatisfactory kind which might serve to relieve itching or numbness, but which would have no effect on the deep tissues. If it were practicable, I would advise manipulation by a skilled masseur, but on account of her means it will be necessary to teach her how to make the necessary movements herself, and I will, therefore, demonstrate them to her and to you at the same time. Beginning at the end of each finger a combination of pinching, kneading and rubbing should be carried out, moving toward the wrist. Four or five minutes should be spent on each finger and at least as much time on the palm and back of the hand, and five minutes more about the wrist. The same manipulation, with greater amplitude, should be practiced on the forearm. She should also try to make movements of pronation and supination. I have advised her to carry out this plan of treatment faithfully for three or four weeks, and if in that way she gets motion enough to satisfy her, there is no reason why I should not be satisfied. On the other hand, if she does not receive the prehensile power of the hand, or if she wishes a more movable hand and forearm than can be obtained by the manipulations which I have suggested, then she can return to the hospital and I will remove the lower end of the ulna and, at the same time she is under the anæsthetic, break up the adhesions in the tendon-sheaths.

BURSITIS OF WRIST—RICE GRAIN BODIES.

The next case is another illustration of injury to the right wrist, but of an entirely different character. The patient is a girl 18 years old, who four years ago fell in the classical way while skating. She broke no bones and was not much disabled at the time, sustaining simply a sprain of the wrist. Three or four months later, however, she began to suffer from pain, weakness and loss of function, and she is now totally incapacitated for her work, that of stenographer.

The circumference of the affected wrist has for three years been greater than that of the other. I find the enlargement to be due to a fluctuating swelling on the anterior surface of the wrist extending upward from the annular ligament. There is also thickening in the palm of the hand. A case similar in many respects to this you saw some days ago in the person of a young man with a tubercular gumma of the arm and a swelling above and below the annular ligament. The gumma was completely excised, the swelling opened exposing freely the bursæ in the palm of the hand and under and above the anterior annular ligament. A quantity of glairy fluid was permitted to escape and the parts were then sewed up carefully. That patient recovered good use of the fingers, but as the case was markedly tubercular, there being a family history of consumption and the patient in fact having incipient phthisis, the general prognosis was not favorable.

In this girl's case, however, there is no family history of tuberculosis, and her general health is excellent. We have the same anatomical condition, dropsy of the synovial bursa about the wrist, but without the tubercular element. As I palpate this swelling there is a sensation of thickened fluid and I fancy that I distinguish in it rice-grain bodies which I have already described and shown to you in similar cases. It is difficult to account for them, and to my mind the only tenable hypothesis of their origin is that a sero-fibrinous exudate is thrown out which precipitates and forms little masses of lymph that are rounded off by friction until their appearance suggests grains of rice from which they have been named.

As I hold up the patient's wrist, you see a very marked protuberance and as I press above the annular ligament, there is a bulging out of the palm of the hand. There is a continuous bursa with a constriction where the annular ligament overrides it, and as I press the contents backward and forward I get the sense as of something—in all probability some larger fibrinous concretion—slipping through beneath the ligament.

In cases of this nature special care must be observed in regard to maintaining asepsis. A longitudinal incision is made in the middle line of the wrist anteriorly and the dissection carried down to a white glistening protuberance which constitutes the wall of the enlarged bursa. As I open into this a quantity of the little rice-grain bodies protrude in a mass, and by pressing on the palm and pulling at the collection with forceps I remove many more ; I can see others still adherent to to the walls of the cavity. I will therefore expose the exterior of the sac more clearly by enlarging the opening, and as an additional aid I will make an exploratory incision into the bursa through the palm of the hand. I dissect away as far as possible the living membrane of the sac, and the rice-grain bodies adherent to it. After irrigating the cavity with a bichloride solution, I close the opening in the wrist with a continuous catgut suture and apply an external antiseptic dressing in the usual manner. (This patient made a perfect recovery.)

NERVE-STRETCHING FOR SCIATICA.

This is the man whom you saw a week ago when I stretched the great sciatic nerve for sciatica. The patient says he has suffered no pain whatever except a little soreness for an hour or two after the operation. He walks easily. We cannot consider the present state of the patient to be a final test of the success of the operation, but he suffered less pain when he regained consciousness from the effects of the ether than he had for some time previous to the operation, and from past experience we may be reasonably sure that he will not have an immediate return of the trouble; so that, whatever the outcome in a year or two, I am sure he will consider that the operation has been to his advantage. I know of no other treatment, medical or surgical, which gives the amount of relief from pain of chronic idiopathic sciatica which the operation of nerve-stretching affords.

THE DUPARCQUE PRIZE.

The *Gazette des hôpitaux* announces that this prize for 1893, amounting to 1,500 francs and a gold medal of the value of 100 francs, is offered by the *Societe de medecine*, of Paris, for the best essay, written or printed, appearing during the year 1891 or 1892, on any subjected connected with tuberculosis. Essays should be sent to the secretary, No. 3 rue de l'Abbaye, Paris, before December 31.

CAPILLARY BRONCHITIS.

Dembitz recommends apomorphine as an expectorant for infants, instead of ipecac. His formula of administration is:

℞ Apomorphini muriat..... r. ⅛ to ½.
Aquæ destil.....f ʒ iv.
Acid. hydrochlorat.....gtt. v.
Syrup. simplis.....f ʒ i
M. Sig. ʒ i every two hours.

Collapse need not be feared, and the apomorphia disturbs digestion less than ipecac. He considers musk the respiratory stimulant *par excellence*. He does not allow the infant to sleep too long at one time, or to lie a length of time in the same position.

If crying makes them cough sometimes, it is all the better. The child should be carried about and its position frequently changed, in order that the secretions may be given less opportunity to settle down and occlude any one part of the smaller tubes. Much mucus may be expelled in producing increased movement of the chest-walls by means of pressure applied to the chest, like artificial respiration.—*Virginia Medical Monthly.*

COMMUNICATIONS.

A FEW OBSERVATIONS ON DISEASES WHICH IMPLICATE THE HIP, KNEE AND ANKLE JOINTS DURING CHILDHOOD.*

By THOMAS H. MANLEY, M. D.,
VISITING-SURGEON TO THE HARLEM HOSPITAL, NEW YORK CITY.

The study of the diseases of the joints has always been full of interest to the observing and progressive student of the healing art; and, when one views the field and notes the vacillating notions from one generation to another which have prevailed with regard to their ætiology, and the varying therapeutic measures resorted to for their relief, our interest is increased, though we must confess that our knowledge of them is not proportionally extended.

Physics and chemistry have placed at our command facilities for accurate observation; yet even among those having the most extensive scope for clinical study, there is nothing like a unanimity of opinion, either with respect to the fundamental causation or most appropriate therapy in those joint lesions so common in children. Hence, among many, the old-timed liniments, salves and lotions, still hold their own; the bandage, splint and weight fixation.

The hip-joint is the deepest lodged and most powerful in the body. The knee-joint has the most extensive ligamentous and tendinous connections, and, for its great size, is the most exposed. The ankle-joint, like the knee, derives its main support from the tendons, which serve as stays. The whole weight of the body, in locomotion, is borne alternately by this articulation. The overlying and subjacent structures play an important rôle in joint disease; it is necessary that they be considered before their pathology is entered into.

In a general way a joint consists of bone, cartilage, synovial membrane, muscles, tendons and ligaments.

Large blood-trunks and nerves of great size pass immediately, posteriorly and anteriorly, to the articulation of the hip and knee. The head of the femur in the cotyloid cavity, is largely supported by and buried under an immense mass of muscular tissue. From the point at which the muscles taper into sinews, the tendons to their inser-

* Read before the Harlem Medical Association January 6, 1892. Dr. M. C. O'Brian, President.

tion into their periosteal attachments, are enclosed in thin, elastic, delicate sheaths, which are designated thecæ. Bursæ, of various size, lie along the tendons.

The epiphyseal ends of the long bones, those parts of the shaft which enter into the formation of the joints in the growing child, are soft, spongy and highly vascular. Recent investigations demonstrate beyond a doubt that minute lymph channels freely penetrate into the cancellous tissue of growing bone. The joints are freely supplied by nerves. As the growth of all shafts of bone is from their ends, their vascular feeders at these points are large and abundant.

Having outlined a few of the gross structures and anatomical elements, the various pathological mutations, of which the joints are the seat, may now be more easily defined and readily comprehended.

We have seen that the joints are passive in function, simply serving a mechanical purpose, as the lungs do one which is chemical, but that they are, on the contrary, acted *upon*.

The three great systems—the vascular, nervous and osseous—are active factors in these maladies. Immobilization, mechanical rest, massage, electricity and exercise, religious invocations, intra-dermic, hypodermic and intra-articular injection of medicated solutions; direct dieting and constitutional remedies; surgical intervention, either palliative or radical; the simple puncture or incision, to the complete sweeping away of the entire joint, have each and all their votaries and partisans.

Thus, we see, swayed by diverse and dissimilar theories—one appealing to psychological influences; another to constitutional measures; another to absolute, enforced rest of the limb; and another to moderate motion, or local stimulation, biding time for arrest of the disease. One class, and until very recently the most numerous, regarded tubercular or scrofulous disease of the articulations, as infectious or incurable, and demanding radical and extreme measures for its relief.

In this conflict of opinion and practice, it is quite evident that anything but a common ground has been reached. We must be largely guided by our own judgment, and in each given case examine minutely into its pathology, then adopting such a therapy as will most rapidly and safely lead to a restoration of healthy function in the articulation or its adjacent structures, a brief consideration of which is here undertaken.

Diseases of the joints are functional or organic, acute or chronic. They are nervous, osseous, arthritic, osteo-arthritic, synovial or muscular in origin.

The best known authors on pathology recognize constitutional causes as the predominating in joint diseases, though there are a few who stoutly maintain that morbid processes in the articulations are often attributable to local injury or traumatic influence, besides those who allege that in tubercular diseases of bone, the bacteria are alone responsible. There are many varieties of arthritic and synovial inflammation which are associated with, or dependent upon, acute febrile diseases, such as rheumatism, scarlet fever, and others. There are other phases of joint incapacity, which seem to be chiefly neurotic in character. And there are cases of restricted motion with incipient degenerative changes in the overlying parts wherein there is actually no morbid process whatever going on within the synovial capsules. It has been conclusively demonstrated that there are separate and well defined motor centres in the brain located on the cortex. It is claimed that they preside over distinct and limited areas of the body.

Disturbances of the normal processes in the cerebro-spinal axis, congenital or acquired, may manifest themselves externally by the non-development, distortion, and wasting of a limb. The long fixed, overstrained state of the extensor muscles, with trophic annoyance will in time result in total loss of function. In all those of chronic spasm of flexor, rotator, or aductor muscles, of a congenital origin, there is associated with it clear evidence of mental deficiency or perversion. This class of cases should scarcely be grouped with joint diseases *ab initio*, but as the deformity resulting is most apparent in the articulations and the joint's utility destroyed, I have thought well to direct attention to it, as a condition whose pathological dependence is remotely situated.

There are many varieties of joint affections which are associated with constitutional disturbances; some of a transient and others of a chronic character.

These diseases may be divided into acute inflammatory and chronic, or diathetic. Among the former we find that in "La Grippe," or influenza, at the outset of an acute attack, very often the knee-joints are painfully sensitive; in acute inflammatory rheumatism (we include that disease which is pathologically characterized by always attacking the fibro-serous structures in the beginning, and thence spreading to contiguous parts), also, cerebro-spinal meningitis, when the disease manifests signs of abatement all the joints of the body are exquisitely sensi-

tive. The exanthematous fevers in childhood are occasionally followed by arthritic diseases.

Among the chronic affections with which articular disease is intimately connected are gout, scrofula, syphilis, and malaria.

Besides constitutional maladies, the health and movement of a joint may be seriously jeopardized by local pathological changes along the muscle planes, the nerves, and blood-trunks, the shafts of bones, and cellular membrane which supports and encloses it. Local changes in the parts which lie between the hip and knee, the knee and the tibio-tarsal articulation or beyond this point induce a partial loss of joint action, and give an impression to the inexperienced that the articulation itself is implicated, while, as a matter of fact, its elements are wholly free from organic change.

These pathological changes in the extra-articulator structures depend either on alterations induced by injury or local diseased conditions. Thus we may witness impaired motion or strength in a joint in close proximity to, or remote from, a fracture. Pressure, laceration, or rupture of nerve, muscular, or vascular tissue gives rise to inflammation in the cellular tissues, to spasm, neuralgia, or paralysis of the muscles supplied by the injured nerve. In periostitis, inflammatory action is propagated outwards by the lymphatics, and efferent vessels to the inter-muscular spaces, and a free plastic exudate is widely diffused in every direction. When this is completely absorbed impediment to motion does not follow; but, if it be in great amount, and becomes organized, the easy, gliding movement of the muscle is interfered with by extensive bands varying in size, direction, and consistency.

Neuralgia, anæsthesia, or hyperæsthesia may extend into a joint by transmission through a contused, torn, or inflamed nerve, or its neurilemma.

So complex and important are the various pathological changes of a constitutional nature located along the shafts of bones, in what may be designated inter-articular spaces, that to enter into each in detail is beyond the scope of my essay. He who is not fully acquainted with them, their precise nature, their histological and molecular composition, and ceaseless changes, with their influence on the nutrition and development of disease of arthritic structures is not qualified to deal with many conditions about the articulations, which, if thoughtlessly or unskillfully treated, will lead to atrophy, to a crippled state, or even loss of a limb.

MALADIES INVOLVING THE HIP-JOINT.

The hip-joint, although the best protected and deepest lodged in the body, in early life is more often the seat of functional and organic disease than any other in the lower extremity. The majority of the affections which interfere with function of this articulation are trivial or temporary, such, for instance, as rheumatism, neuralgia, or idiopathic inter-muscular inflammation of an evanescent character. From traumatisms arise contusions, moderate cellulitis, or synovitis.

In strumous children tubercular disease in this joint occasionally works great havoc, attacking in varying degrees the osseous, arthritic, and synovial tissues, and ending in serious cases, in distortion, anchylosis, shortening of the limb, or even the loss of life.

For a long time it has been well known that there was a close clinical and pathological affinity between ulcerative disease in the joints and pulmonary phthisis, but not until recently has it been definitely determined by the microscope that the pathogenic germ of each is identical. It was supposed that the relation between pulmonary and strumous disease in the joints having been established, hereafter our therapeutic resources would be extended, and we would proceed to treat joint diseases by precise and scientific methods. Accordingly, there has been no end to the theories which have been wrought to explain the pathology of this mysterious disease, and plans of treatment for its arrest or extinction. Its heredity had been denied. It was said to be infectious and contagious. Some alleged that it was disseminated by the lymphatics; others, by the vascular system; that it might enter the system through any of the various orifices in the body—the mouth, rectum, urethra, or vagina,—through the atmosphere, ingesta, or semen, through an abrasion in the integuments or mucous membranes, and even through the placental circulation to the fœtus.

Hence, a tubercular disease in glandular or other tissue, when accessible to the scalpel, the gouge, or cautery, was eagerly sought and swept away. The discovery of the tubercular bacillus, and the new therapy which was invoked to meet it, gave an immense impetus to operative surgery, and enormously swelled the number of cases demanding surgical intervention. In fact, tubercular disease of nearly every organ except the lung came to be regarded as no longer a malady to be managed by the physician, but belonging exclusively to the surgeon.

After all, the main question has not yet been answered, and many of the allegations of modern enthusiastic investigators rest on

such unstable deductions that we are, in this regard, at present, in a state of great uncertainty.

No one has yet demonstrated to us why tuberculosis manifests a special predilection for the lymphatics of the neck and the osseous system in childhood, and the pulmonary parenchyma in the adults.

It is a great mistake to assume that every phase of tubercular invasion of any of the structures going to make up the articulation at the hip, is "hip-joint disease." In medical nomenclature the term is often vague and meaningless, but to the laity of serious import. Now, if we proceed, when we are assured that our little patient has tubercular implication at the hip, with active, or misdirected, mechanical treatment, we may induce a condition as bad or worse than the one we are endeavoring to prevent, and may cripple our patient for the remainder of his life.

Tubercular disease may manifest itself in the anatomical elements of the hip-joint, in manifold phases, as it does in the pulmonary organs. The invasion may be confined to a very limited area, never passing from the inflammatory to the ulcerative stage, and giving rise to little, if any, inconvenience. In fact, it may be entirely painless. In a second class of cases, the synovial capsule alone is involved, and so we will have an effusion. This, as in the preceding phase, undergoing resolution, the effused fluid being absorbed and function regained.

With the third class, the disease is serious. Here we will have participation of the osseous and cartilaginous elements, the perichondrium and periosteum. It will generally be noted with this group that from the very onset the nutritive processes are at a low state and the system is saturated with tubercle. Here the germ action gives rise to a low grade of diffuse inflammation which indiscriminately involves all the tissues, but is specially destructive to the epiphyseal ends of the bone. The inflammatory action is but feebly resisted by vital processes and in a short time takes in ulcerative changes, reducing the tissues to a caseous, pulpy, or fluid consistence. Now, the ultimate outcome with these cases will depend on the patient's inherent resisting power, surroundings and treatment.

The best that we can accomplish when the disease takes on these great changes, is to arrest it or modify its violence, as we cannot restore what it has already destroyed. As the fluid which accumulates in these cases is not septic and if not found in too great quantities may be absorbed with impunity, unless it is in close contact with necrosed bone, and is disposed to infiltrate healthy tissues, it should be left undisturbed within its capsule.

In that class of cases of the tubercular invasion at the ileo-femoral articulation in which the area involved is limited, the symptoms announcing its advent will vary in duration according to the situation and the structures which are implicated will depend on the amount of resistance which it encounters, or whether congestion runs into inflammation or inflammation into ulceration. When the periosteum is the part primarily invaded, pain is always present and of an aggravated description. Should the original diseased focus lie along the muscle sheath and outside of the capsule, not infrequently an abscess will form that may either impede absorption or, in time, point and break. With final collapse of its walls and the cessation of suppuration, the full functional use of the joint will be rapidly regained. In the second class of tubercular affection at the hip, the synovial membrane and the fibro-cartilaginous structures are the principal seat of pathological changes. The synovial fluid may be secreted in such quantities as to induce pressure on contiguous vessels; hence, seriously interfere with the nutrition, principally of the arthritic and osteo-arthritic structures. When synovial inflammation of this description fails to undergo resolution, the accumulated fluid may take on molecular changes of a chemical or bacterial character.

In mild types of tubercular synovitis in a well-fed, vigorous subject, there is no reason to assume that it is not amenable solely to appropriate constitutional and local remedies.

The third and last type of tuberculosis involving the hip, that which usually terminates in necrosis, anchylosis, or spontaneous dislocation, considerable shortening of the limb may occur. Death of the patient is seldom or never encountered, except in those of a pronounced inherited strumous cachexia, or acquired through degenerating influences, as bad air, non-nutritious and insufficient diet. With patients of this description, the advance of tuberculous changes is usually rapid and destructive. It seldom abates until some important anatomical structure has been seriously compromised, the head of the bone being often destroyed, the osseous floor of the cotyloid-cavity is occupied by caries, and the perichondrium, cartilage and ligaments having undergone partial or extensive disorganization. While these changes have been advancing in the anatomical elements of the joints in consequence of the enormous cellular hyperplasia which is pro-

pagated from the fibrous elements at the articulation, the cellular tissues and circumjacent structures, present a tumid, swollen appearance. The weakened walls of the main venous trunks, either from pressure or want of elasticity, give rise to stasis in the capillary circulation, so that a sort of inflammatory œdema is always noticed in severe cases.

Through the free plastic exudate, so freely thrown out and partly organized in the intermuscular spaces, and the prolonged inactive state of the limb, the muscle-sheaths fuse together. The contained muscle atrophies, contracts, or if forcibly restrained from action over a very protracted period of time, will undergo fatty, or fibrous interstitial degeneration.

The nerve-cylinders, like the arterial walls which pass in close proximity to the femoral head, manifest great resisting power and, except as a consequence of considerable pressure or tension, escape morbid changes.

The lymphatic glands form the entire lower extremity and the ileo-femoral articulation are drained through two systems of absorbent vessels; the peripheral and the deep. In superficial, tubercular implication at the hip, none but the superficial inguinal glands will become turgescent and greatly enlarged; but when the osteo-arthritic elements are involved, both the inguinal and the deep pelvic, mesenteric and retro-peritoneal glands, through septic infection carried along their lower lymph-channels, are greatly increased in volume, either by an inflammatory exudate into their stroma or by hypertrophic changes in the cellular elements, and great increase in their intercellular structure.

As a result of long-continued pain and exhaustic drain on the economy in hip-joint tuberculosis, or the same pathological process in any other of the major articulations, unless the system is well fortified and correct treatment is instituted, the internal organs will in time present signs of participation, particularly the kidney, by waxy degeneration.

Does tuberculous disease involving the coxo-femoral articulation or other joints arise from morbid changes *de novo* in the anatomical elements called into activity by certain constitutional or local conditiens, or does it depend on a certain specific infection, the germs of which gaining direct access through the ingesta or otherwise, and carried to that part in which morbid phenomena first makes their appearance?

If the theory of the contagiousness of tuberculosis rests on a substantial basis which has been irrefutably demonstrated, then we must answer that this osteo-arthritic disease always originates solely through an acquired contagion, the virulence of which is spent in early life on the articular structures.

It will be most commonly found that the subjects of tubercular disease in the joints inherit a strumous diathesis, have a frail constitution and, though frequently large eaters, they poorly assimilate their food.

Although, perhaps, the most serious and rebellious types of joint disease may be found among little children, crowded together and badly fed, yet it is of frequent occurrence among the opulent and in the most isolated sections of the country. Moreover, we seldom see children from parents who have lingered for months or years in their homes before they died of tubercular consumption. It may be said that the outbreak of this disease in the articulations arises from a local impression on a general condition; that certain children of a strumous diathesis may, after any of the exanthematous diseases, an injury, or after a severe synovitis or arthritis arising from cold which will fail to resolve, fall victims to tubercular disease in a joint.

In tubercular affections of the hip, or other joints, is there danger of the bacilli being taken up by blood vessels or lymph channels and being disseminated through the system, and carried to distant internal organs, as the lungs, the brain, or the kidney? If the disease appears first locally, with a tendency to a general diffusion, then, certainly, its early and thorough eradication is imperative. But there is no proof that visceral implication ever follows, as a secondary event, when a joint is diseased. On the contrary, it is alleged by some that when there are symptoms of tubercular invasion of the pulmonary parenchyma, and a tuberculous mass of bone or broken-down tissue is removed by complete excision, the pulmonary malady takes on a cumulative phase, gathers renewed violence, and promptly ends in the loss of life.

During the acute stages of tubercular disease in the hip-joint there are many pathological phenomena present in varying degrees which require an intimate knowledge of them if we would intelligently direct such measures of relief as will be attended with the greatest and most enduring benefit.

We will notice that in every case of tubercular disease at the hip-joint, regardless of whether there be loss of bone or dislocation, when the limb has been long immobilized, there will be more or less shortening. In other words, when, in the treatment of any morbid condition at the hip-joint, a fixation-apparatus is adjusted which permanently im-

mobilizes the growing limb, the enforced inaction and pressure of bandages or straps on the large blood-trunks will cause an arrest of development, or at least so retard normal growth that when the arthritic disease has come to a halt it will be found that the limb on the affected side will be wanting considerably in length when compared with its fellow on the other side of the body.

When the disease has been so destructive as to cause the disorganization of the *ligamentum teres* and the capsule, we will have dislocation of the head of the femur on the dorsum of the ileum, the acetabulum becoming obliterated, a new hollow for the dislodged bone being provided.

When the disease has passed from the inflammatory into the ulcerative stage, and its violence has been spent mainly on the cancellous or compact elements, the necrosed bone, if not removed by surgical intervention, may undergo a gradual disintegration, the non-septic fluid, fatty and albuminoid elements, being taken up by the absorbents and the residue as sequestra and fragments making their way through the soft parts, through cloacæ in the new periosteal wall or sinuses, which will remain open until all of morbid material is thrown off.

[To be continued in the next issue.]

THE NECESSITY OF SURGICAL KNOWLEDGE IN GENERAL PRACTICE.*

By R. J. JENKINS, M. D.,
SHELBYVILLE, IND.

In the exigencies of an active general practice in country districts, the general practitioner is often confronted with surgical injuries obliging him to render whatever assistance and resources may be available for the relief of suffering and the saving of life.

Such occasions bring to the test the poise of mind and practical character of the physician; and his reputation at such times may be weighed in the balance, and turned fortunately in his favor or unhappily against him.

It is in the experience of every practitioner to meet with surgical injuries requiring immediate attention, and sometimes in order to succeed in bringing needed relief, it is necessary that the medical attendant should be possessed of the most consummate knowledge and skill.

A large majority of the injuries occurring in the practice of the country doctor are so severe, and attended by so much danger, that the arrival of a specialist from a distant metropolis cannot be awaited; and whatever is done under such circumstances to lessen human suffering and to insure life can only come at the hands and good sense of the well-equipped, general practitioner.

The casualties occurring in a busy country practice have so often brought me face to face with living surgical problems. I trust a reference to some of them which I may be able to recall might possibly be of benefit to some of the younger members of our profession who are engaged in the general practice of medicine.

In a village about twenty miles distance from this place I practiced medicine for fifteen years, and many mishaps occurred to the people of that community in that time, and inasmuch as there were three stone quarries near by, in which many men were employed, and where such destructive explosives as dynamite are used, it can be conceived that many accidents would necessarily occur requiring prompt surgical relief.

In support of the proposition that gives this paper its title, I will briefly refer to only a limited number of surgical cases coming under my care as a general practitioner.

Twice in those years major operations were performed by myself, the necessity of which was caused by premature explosions of dynamite.

One case was the amputation of thigh at junction of the middle with its upper third; the other of the hand.

Both patients made a fair recovery, except that necrosis of the end of the femur occurred in the patient who had leg removed, which might have been avoided had the operator been more familiar with the details of the operation—and the patient would have certainly lived if his medical attendant had possessed the knowledge—making him see the danger in delaying the resection of the diseased bone, which was not done until the patient was overwhelmed with septicæmia.

Among the many remarkable injuries demanding my assistance in that time was a gunshot-wound of the elbow, penetrating the joint, passing through the capsule and up beneath the periosteum, making its exit near the shoulder-joint.

The arm was removed in this case and the boy made a complete recovery.

Four cases of emphysema (who like the woman in the Scripture had suffered much at the hands of the physician) were effectually

* Read before the Mitchell District Society, December 18, 1891.

aspirated, and all save one was restored to moderate health.

A cause for regret with me lies in the fact that I did three craniotomies on living children, the urgency of which was demanded by small pelvis and exhaustion of parturient females.

Taking a retrospect of these bloody transactions amounting almost to tragedies, how much better it might have been should I have known how to do Cæsarean section.

Other cases requiring immediate attention and depending on me, a general practitioner, were three cases of hydrocele, with acute perichorditis, and as one man died in that vicinity from the effects of a paracentitis scrotalis performed by a surgeon of some reputation in a neighboring city, it is easy to see how that circumstance militated against the operation, and with what trepidation I undertook the performance of such a plain duty.

The question of time is all-important in cases which from this severity demands immediate attention.

Procrastination is the most common element of danger; there could be no proper excuse for not being able to evacuate the bladder of a parturient female, which if not done might cause a rupture of that viscus during the severe pains of labor; yet, I once heard related by a professor to a class of medical students, that he was called twenty miles in the country to relieve the patient of a reputable physician in this condition.

No doctor, therefore, should be unprepared for a duty of this kind; a good medium size aseptic catheter should have a place in the pocket case of every physician, and he should become so expert in its use that he could introduce it with facility and without pain; and it should not be necessary to uncover a female whenever in such cases it must be used.

Other cases requiring immediate attention on the part of the family physician, and to which he should bring his knowledge of surgery, are: gun-shot and incised wounds of the viscera of the body, especially wounds of the abdomen; strangulated hernia and intussusception or internal strangulation of the bowels, also come under this head; and are so grave in their nature as to hold out no prospect for life, only when vigorous surgery is done.

In the same class belong sudden compression of brain, hæmorrhage from whatsoever source, foreign bodies in the larynx, trachea, or bronchi, all quickly ending in death if the resources of surgery are not employed to save. Also in the department of obstetrics, where for the lack of this knowledge and skill, death has swayed his sceptre for centuries past.

Professor Nausbaurn, I believe it was, in speaking of the necessity of enterotomy and gastrotomy in cases of internal strangulation and other abdominal sections said that "thousands now lie in their graves, who have died from these distressing conditions, while surgeons stood by as mere lookers-on, unable to help their patients."

Delay in this class of cases is to be condemned.

Most of us perhaps in this Assembly, can call to mind one or more unfortunate occurrences relating to cases of this kind in our own practice, or in that of neighboring colleagues.

Well do I remember with regret a child with a traumatic peritonitis, who was dosed with opium day and night for five long days without any surcease from pain; I had been told almost poetically that this drug was the "Anchor Sheet" in this disease, but it failed utterly to bring relief; but seemed to make matters worse, and a proposition made by an old and reputable physician, who was called in consultation, that I had prejudiced the prospect for my patient's recovery because in the beginning of the sickness I had given the child a mild cathartic seems to have met its fall almost at the threshold of its utterance, because of the very decided manner in which abdominal surgeons and others give salines freely and with undoubted success at this time.

Under the low rate of mortality in the operation of laparotomy at the present, even where it is necessary to perform ovariotomy and make ablation of tubes, a case of simple traumatic peritonitis ought to be restored to health by the resources of modern aseptic and antiseptic surgery.

As regards laparotomy, formerly the mortality was so great that no one not specially skilled in abdominal surgery would think of undertaking so formidable an operation; but, when surgeons of moderate skill save seventy per cent. of ordinary abdominal sections, I maintain that in severe injuries, where the delay would bring certain death, the general practitioner should be prepared for such contingencies and should give such relief as is ordinarily given by surgeons under circumstances of this kind.

In order to emphasize the proposition that the practitioner should do the most capital operations, under certain conditions it is only necessary to refer to a limited number of Cæsarean sections that have been done

by persons without title or rank, all of which have made phenomenal recoveries, and some of them lived happily many years afterwards.

Dr. Michaelis in the Southern Medical Journal, 1839, reports the case of a woman upon whom the Cæsarean section was successfully performed four times; the first operation was performed in June, 1826, the woman being then in her twenty-ninth year, the second in January, 1830; the third in March, 1832: and the fourth on June 27th, 1836, after the patient had been in labor three days.

Another case, in which a drunken negress, who acted as midwife, on being called to a black girl in her first labor, which was natural, took a sharp knife, and without any reason to justify her conduct, laid open the abdomen and womb, and took therefrom a living child. This girl speedily recovered, with no other inconvenience except a slight incontinence of urine.

Self-inflicted sections of the abdomen have been done, and the patient lived several years afterwards.

Paul F. Eve, in his remakable cases of surgery, relates a case of this kind in which the woman being in labor, in order to expedite matters did a Cæsarean section upon herself with a broken butcher knife; and although a part of the intestines came out of the wound, and was returned in a septic condition, the patient got well and lived many years afterwards.

These cases are only referred to to show the extraordinary endurance of the human system, and the curious and almost incredible injuries it has sustained and recovered from in the most gratifying manner.

Thus it may be seen that whatever menace may be present, and however proper it is to possess the instinct and training of the surgeon, it is to be remembered that most of the operations alluded to in this paper were performed by the general practitioner, or other persons whose learning or experience in surgery had little to do with the happy results.

Two curious cases in the practice of colleagues of mine, and the hopelessness of which would have justified Cæsarean section, were permitted to die undelivered. I am not informed whether this last prospect was held out to either of them, but be that as it may, these two cases are the only ones of this kind of which I have any knowledge in which the patient died in this peculiar condition.

Both of these cases occurred in the practice of gentlemen who stand deservedly high in their respective communities, both with physicians and laity; and it has always been a matter of wonder to me why these cases did not get the benefit of abdominal sections.

Numerous other and less important examples demanding surgical knowledge in the general practitioner and coming under the writer's notice, might be referred to at this time, but as you have been very patient with me, I will refrain from a discussion of the lesser affairs of surgery, which embrace lesions of the soft parts, fractures and dislocations, all of which properly belong to the domain of surgery; yet, by the very nature of environment and situation, a majority of these injuries must necessarily come under the care of the general practitioner. All of us should be prepared to do the most capital operations when from severe traumatism or other causes, life would be put in jeopardy by much delay; also little ablations or other small operations which relate to the less important lesions, and which for their relief no great risks are taken.

In short, we should know how best to promote the welfare of our patients, and if there is a reasonable doubt about undertaking any operation, the very best counsel should be had that can be readily obtained.

Finally, if there is anything else to do in the perplexities that confront us in the general practice, it is to keep cool, carry our conscience and God with us in every place of danger, and do no needless operations, remembering that our mission is to save and not destroy.

Keeping in mind the good involved in the right performance of small duties before aspiring to the honor and dignity of greater, and in our efforts to save human life, an adherence to these principles will bring us a large measure of success.

INTRA-PULMONARY INJECTIONS OF THYMOL IN PULMONARY GANGRENE.

Dr. O. Hewelke, of Varsovie, Poland (*La Semaine medicale*, No. 49, 1861), has successfully treated a case of pulmonary gangrene by intra-thoracid injections of a 1 : 300 or 1 : 200 solution of thymol made with a syringe, having a needle five to seven centimeters long, into the cavern. The results were immediate. The needle was pushed through the intercostal space corresponding to the spot affected. The expectoration became more abundant, the fetidity of sputa diminished, and the temperature fell quite considerably. With daily repetition of these injections the general and local symptoms so improved progressively as to more or less soon completely disappear.

MY LAST ONE HUNDRED OBSTETRICAL CASES.*

By G. C. LEWIS, M. D.,
FAIRBURY, ILL.

Of this number 90 were delivered perfectly normally; 47 were males and 53 females. There were two pairs of twins; one boys and one girls. Each pair had one placenta with two cords. The majority of the children were born at night, as is usually the case. Among the complicated cases were puerperal convulsions, ruptured perinæums, retained placentas, breech presentations, footlings, those requiring instrumental delivery, craniotomy, face and transverse presentations.

The normal cases we shall consider only in regard to their treatment. If the os uteri is slow in dilating, I give a capsule filled with chloral hydrate every fifteen or twenty minutes until the os is soft and patulous and perfectly dilated. If then the uterine contractions are not vigorous enough to accomplish the object intended, I do not hesitate to give a drachm of the fluid extract of ergot, if I can be reasonably sure that the longitudinal muscular fibres of the uterus will continue to contract and cause the circular fibres of the os to dilate, thereby securing the right of way for the descent of the child and the "vis a tergo" of the uterus will cause the child's head to take possession of the way secured, and descend through the bony pelvis. When the os is fully dilated, I rupture the membranes, as they then serve only to delay the second stage of labor. When the head impinges on the perinæum and causes it to bulge, I insert the index and middle fingers of right hand into the rectum (the woman lying supinely), and receive the child's head in palm of same hand, an thus cause the head to hug the pubic arch, and in this manner prevent rupture of the perinæum, and also be able to keep the head elevated so that no amniotic fluid, blood, etc., can enter its mouth when it attempts to gasp for breath. The umbilical cord should be tied in two places and cut between. The second ligature retains more blood in placenta, and the uterus has a firmer body around which to contract. I use Credé's method to expel the placenta. With left hand over the abdomen, kneading the womb, and with umbilical cord around two fingers of right hand, I have the patient hold her breath, and bear down gently, at regular intervals of a few seconds, and in a few minutes the placenta is expelled. By carefully following this method, I have yet to encounter my first case of post-partum hæmorrhage. After the placenta has passed from the uterus and through the vagina, let it lie there until all secundines have been removed. Sometimes there are none; at other times they are three feet long, and often very easily broken unless great care is taken. I believe, when the secundines are retained and become decomposed in uterus, they often are the cause of puerperal septicæmia. In the majority of medical colleges students are taught to give ergot only in the third stage of labor. Although it is good to prevent hæmorrhage, yet my experience leads me to believe it causes the uterus to firmly grasp the placenta, and cause the circular fibres to so contract that its removal is greatly retarded, besides causing unnecessary afterpains. In three cases do I well remember where a midwife, armed with "a certificate to practice medicine in the State of Illinois," had given so much ergot, to facilitate the expulsion of the placenta, that the patients had to be anæsthetized in order to relax the firm grasp of the uterus.

The anæsthetic I always use is the A. C. E. mixture—alcohol, chloroform and ether—in the proportion of 1, 2 and 3, with Allis' inhaler, so that the patient can get fresh air at every breath.

In anæsthetizing a patient, the pulsation of the carotid arteries can be carefully felt by the one giving the anæsthetic, much easier than the radial, and does not cause so much anxiety on the part of the friends. Pulsation and respiration are the two main things to be carefully noticed in administering an anæsthetic.

I have met with two cases of ruptured perinæum: one treated by a midwife and one in instrumental labor. I sewed up the lacerations with silk within an hour after they occurred, and each one made a perfect recovery.

I have met in consultation one case of puerperal convulsions, and may the good Lord deliver me from ever seeing another. After the attending physician had manfully battled with them for 18 long hours, I was hastily summoned to come and deliver with instruments—hoping the convulsions would then cease. I delivered her in half an hour. I then suggested the removal of the anæsthetic only to see her have another terrific and heart-rending convulsion. In spite of all we could do the convulsions persisted in coming until death came to her relief.

* Read before the North Central Illinois Medical Association, at Streater, Ills., Dec. 1 and 2, 1891.

PLACENTA PRÆVIA.

This case, primipara, aged 33, was also met with in consultation. After the attending physician waited thirty hours, the patient becoming completely exhausted from loss of blood, I was hastily summoned, made an examination and discovered a part of the placenta attached to the os and a portion descended into vagina. Tamponing was suggested and apparently worked well for a while, but soon the patient turned deathly pale, no radial pulse, sighing respiration and to all appearances dying. Tampon was hastily removed, and I actually had to tear my way through the presenting placenta to reach the child's head; the case was desperate. There had been no strong uterine contraction at any time. So forceps were quickly adjusted and the child's head brought down and engaged in pelvis. Hæmorrhage then ceased. Stimulants and ergot were given, A. C. E. also given by inhalation, traction on forceps kept up; but the head was so large, pelvis so small, that the head became completely locked. Craniotomy had to be resorted to. In a short time delivered her. The dead child weighed 12 pounds. The patient made a good recovery. Seldom do we encounter placenta prævia and have to perform craniotomy in the same case. I have attended this lady twice since. In one, labor was natural; but the last was instrumental—owing to lack of uterine contractions. This occurred just a few weeks ago.

PODALIC PRESENTATION.

One foot presenting; uterine contraction very powerful. Brought down second foot. Body was quickly and easily born, and expected the head to follow at next pain, but instead the os contracted terrifically and was choking the child to death. I hastily inserted my hand to relax the os only to have my hand grasped and squeezed as in a vise. After next pain ceased, quickly removed my hand, realizing that neither the child nor I could stand such compression. I gave A. C. E. and the os immediately relaxed, and after a few pains, child was born, but all efforts to resuscitate it failed.

TRANSVERSE PRESENTATION.

One night I was called ten miles into the country to attend a lady. As soon as I entered the house I saw something was wrong. Upon examination I found a very pendulous abdomen and the child lying transversely. It looked as if the mother had a child's hammock with a child in it bound to her body. The abdominal muscles were so distended and the fundus of the uterus so anteverted that the womb seemed to have turned a complete somersault, and the child hung without and below the pelvis of the mother. She could not sit down without the fundus touching the chair. I took a sheet, placed it under the pendulous abdomen and lifted it upward above the pelvis and fastened the ends with safely-pins. The os uteri was partially dilated, size of silver quarter; gave chloral and waited for relaxation of os. In four hours it was dilated sufficiently to introduce two fingers; then by means of external and internal manipulations succeeded in converting the transverse presentation into a vertex. After that labor was normal. Fine girl babe the outcome. In getting the history of this case I learned that when she was four months pregnant, she accidentally stumbled and fell headlong on her face. I thought possibly that that might be the cause and beginning of the development of the child transversely as described above.

The second case of transverse presentation was seen in consultation. The physician in attendance had delivered the parturient lady of one child and proceeded to remove the placenta, when to his surprise he discovered another child, but being unable to diagnose the presentation, sent for help. I arrived in a short time, diagnosed transverse presentation, and with one hand in vagina and the other over the abdomen succeeded in converting it into a vertex presentation and child was soon born.

PROLAPSE OF THE UMBILICAL CORD.

Two weeks ago met a case of this kind. First examination revealed nothing abnormal, and os dilated to the size of a silver dollar. Waited an hour and examined again: os fully dilated and head presenting and beginning to descend. Pains were working nicely. Then half an hour examined again to find a loop of the umbilical cord lying in vagina. I inserted two fingers carried the loop up along side of child's head and above it. Kneaded uterus with left hand and as the pain came on, slowly slipped my fingers away, the loop of cord persisted in following several times, but finally succeeded in having it retained, and child's head descended into the pelvis and prevented any other trouble. A girl babe was born in half an hour later. Umbilical cord has often been found wound once or twice around child's neck. As soon as head is born I pass two fingers between the child's neck and cord and hold it away from the trachea, although by doing this it will press more tightly on the back of the child's neck; but that does not make any particular difference

so long as the arteries and veins and trachea are not constricted.

THE FORCEPS.

In regard to the use of the obstetrical forceps, I believe as much as any one in "letting nature have its course" but there are times when nature fails and the accoucheur must come to her aid. Although a man may die from smallpox after being vaccinated, or may fall from grace after having joined church, yet that does not condemn vaccination nor religion; and because a woman may once in several hundred cases succumb to the use of obstetrical forceps, yet that does not condemn their use in properly selected cases.

Statistics, in the leading hospitals of England prove that whereas thirty years ago instruments were used only once in 310 cases, now they are used once in 8 cases. It is thus very apparent what a great change has taken place. Just seven months ago do I well remember having been summoned by a messenger, telling me to come with instruments and chloroform. Upon entering the house the attending physician said, "Glad to see you, doctor, we are all worn out." The lady in confinement asked, "Doctor can't you do something to relieve me I have been this way for fifty-two hours." "Fifty-two hours," I repeated. "Yes, fifty-two hours," exclaimed her mother and a couple of other attendants. I made an examination, found os uteri fully dilated, but complete uterine inertia. Every body and every thing were literally "played out." As the parties were quite wealthy and very desirous of an heir, I explained to them that I could deliver her all right but feared the child would be still born. Patient was anæsthetized, then handed the A. C. E. and inhaler to the other physician, with the lady in a recumbent position across the bed, and each knee supported by an attendant, I adjusted my Elliot forceps. They had to be inserted high up into the uterus to grasp the child's head, and then it took just one solid hour of firm, steady traction, with intervals of relaxing forceps to relieve pressure on child's head, until child was born. I thought child was dead, but hastily pressed my lips against those of the child and gently inflated its lungs, then compressed its thorax with my hands and expelled the air, then repeated the inflating and compressing as before, and kept on doing this for several minutes when to our great joy the child gasped for breath and soon rallied. The lady was a primipara, aged 23, and gave birth to a 13-pound boy. The attending physician slunk away as if conscious of criminal neglect. After the mother and child were properly cared for, and comfortably lying together in bed, I could scarcely suppress my indignation and condemnation on account of the way that lady had been made to needlessly suffer. I boldly told them all that she could have been delivered 24 hours sooner and with great deal less risk to the child. The attending physician had always advocated "letting nature have her way." He had never been known to use instruments himself, but was glad enough on this occasion to have some one assist nature and let him out. I have never let a woman suffer over 18 hours and never expect to, if it is in my power to give her relief.

I remember two couple who were married within twenty-four hours of each other, by the same minister, and just a year later and within twenty-four hours of each other I attended the ladies in confinement, and each required instrumental delivery. A bright girl babe the result of the first couple's marriage, and a fine boy of the second. My last case of instrumental labor was just two weeks ago. Primipara, aged 32, and weighing 250 pounds. After waiting twelve hours, pains having been stimulated with ergot and pressure over abdomen, the child's head had descended to the perinæum, and for three hours remained in same position. Pains were regular, but inefficient. Told the husband and wife I could soon relieve her with instruments, and they readily consented. My instruments were at hand, for I never attended a case of confinement in country without taking them with me. This was the first case on which I ever used instruments without first anæsthetizing the patient; but as the head was so low, concluded to try without the anæsthetic, although I had her husband hold bottle and inhaler in hand, ready if necessary.

The lady was bemoaning her condition and thought she had a harder time than most women. With each knee supported by an assistant, I easily and quickly adjusted the forceps, and in just five minutes by the clock a bright girl baby was born, when the mother exclaimed, "Oh! if it is no harder than that don't care how many more I have."

In every case of confinement, after the child is handed over to the nurse and placenta removed, I invariably change everything about the bed that is soiled; have a warm change of clothing for the patient, and a change of linen for the bed; bathe the parts with a soft cloth, dry them and anoint them, (all this can be done under cover) then apply a large cloth to the vulva, fastened in front and behind with safety-pins, to her undergarment. I usually let the patient have her own prefer-

ence whether she shall wear a bandage or not. If one is applied, have it done so neatly, and secure upper border of the band to her undergarment, to prevent slipping down, and secure lower border to the ends of the cloth intended for the absorption of the lochial discharge. When this is all done and the patient lying comfortably in bed, she feels as though she was in the seventh heaven. The after-treatment should be carefully directed. The parts should be carefully bathed, dried and anointed with vaseline two or three times a day, and a clean, warm cloth pinned on each time. I believe in *asepsis* rather than *antisepsis*, and that "cleanliness is the next thing to godliness.' When I leave a case of confinement, I tell them I will be around again in two or three days; but if anything should go wrong to let me know of it. I thus can make it a point to see how the after-treatment is carried out. If anything has gone wrong you can thus forestall it and nip it in the bud. By doing this, you can often avert a gathered breast, which, to some women, is more painful than giving birth to a child. You can learn the condition of bowels and kidneys of both mother and child. I have had to operate for phimosis at the second visit, when nurse said, "Child cried nearly all time and had passed no water." If any symptoms arise of that most dreaded disease, "puerperal septicæmia," or child-bed fever, they will be recognizable by that time, and you must be on the alert to adopt such measures as will suppress them, or at least render them more mild. Your presence the second time makes the woman feel you have taken a great interest in her case. Charge nothing for the after-visit. Besides all this, even if you find everything to be as it should be on your second visit, you have a better opportunity for studying human nature and meditating upon the future possibilities of the precious babe lying so sweetly by its mother's side. While thus meditating you will, perhaps, feel a desire to express your thoughts in the language of the poet:

> "Ah, blessings on those little hands,
> Whose work is yet undone!
> And blessings on those little feet,
> Whose race is yet unrun!
> And blessings on the little brain,
> That has not learned to plan!
> Whate'er the future holds in store,
> God bless the 'coming man!'"

Two fruitful causes of constipation mentioned by Dr. Lange are eating too much and chewing too little.

A CASE OF DIABETIC COMA.

By J. M. SHAFFER, M. D.
KEOKUK, IOWA.

From its rarity, its unknown cause and its speedy termination, this case is given the profession to profit withal.

Willie B——, white, aged 14 years; tall, slender, erect; history of constitutional or hereditary taint, negative; all moral and material surroundings of best character. It was the school vacation; he was a close student and had made some progress in Latin grammar. Had never been ill. December 27, 1891, parents noticed that he drank three or four glasses of water at dinner; that he passed a half chamberful of water during the night; drank water at night and mentioned thirst during day. Symptoms continued, were remarked upon, but thought to be mutually cause and effect. Was skating January 4, 1891, and engaging heartily in the winter sports of the holidays. On the 5th, exhibited dyspeptic symptoms which were promptly met; tendency to constipation. Other symptoms were of the nervous character accompanying *la grippe* epidemic here, and a member of the family suffering with it. The excessive micturition and thirst continue. 8th, labored respiration, mostly thoracic; decided hebetude. 9th, at turn of night, moribund; stimulants and external applications, rallied; temperature from 96° to 98.5°. Enough consciousness six hours before death to attempt to protrude tongue. Cried out several times, and being spoken to, said: "It hurts." Died comatose at 10½ A. M. of January 9th, or about ninety-six hours after treatment begun. Urine passed evening of 8th gave this analysis: Color, limpid; reaction, acid; specific gravity, 1.032; loaded with sugar, one-quarter part by Prof. Haine's test and by improved bismuth test.

On the occurrence of a similar case with the two symptoms—excessive thirst and large urinary discharge—it might be well to produce stasis by opium, just short of narcotism, to stop the exhaustive process and gain time to establish nutritive action by alcohol and concentrated food by the mouth and by enema.

An ounce of camphor dissolved in three ounces of turpentine has been used in Columbia Hospital for Women to check secretion of milk in mastitis. It relieves pain, diminishes induration, and reduces inflammation. Care should be taken, that the part should not be so tightly covered that the application shall produce irritation of the surface.

SOCIETY REPORTS.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, December 15th, 1891.

T. D. Davis, M. D., President, in the Chair.

Subject for discussion, Syphilis.

Dr. Thomas: It was but a few days ago that I received a notice requesting me to open a discussion at this meeting. It is usual to open the discussion with a well-digested paper. The time has been so short that it would be impossible for me to prepare anything worthy of the dignity of a "paper." What I shall present will be more in the form of a syllabus, expecting you to elaborate.

1st. How long is syphilis contagious?

The profession, as a rule, does not have definite and uniform opinions upon this point. Judging from remarks that I have heard made at various times, some believe that there is no limit to the *contagious* character of syphilis, forgetting that the disease is a self-limited one.

Possibly I can formulate my views better by reporting three cases, from a number of similar ones, from my case-book, as follows:

Case I. Mrs. A. married, when the man who became her husband was in the secondary (end of first year) stage of syphilis. In ten months afterward she gave birth to a very large (weighing 12 pounds) and healthy looking child. The child was still-born, not from syphilis, but from asphyxia, owing to tardy delivery of the head, the presentation being pelvic. The case was in charge of a midwife, and when I arrived upon the scene I found a dead child hanging from the vulva.

In nine months after she gave birth to a macerated fœtus of five months utero-gestation.

In another eleven months she again gave birth to a macerated fœtus of seven months utero-gestation.

In one and a half years more she gave birth to a full term and healthy looking child. In a short time this child developed a papular syphilide. It remained under my care for two years, and is to-day a large and healthy looking lad.

In another twenty-one months she gave birth to a fine child that never presented the least suspicion of syphilis.

In two years more she gave birth to a healthy child, which is now nearly three years old, and has never shown any evidence of syphilis.

Mrs. A. has been under my continuous observation since her first accouchement. I have been unable to get a history of primary lesion or secondary symptoms in her case; she passed through them without her knowledge, but I have treated her for serious tertiary lesions, such as deep ulcers on the posterior fauces, headache and syphilitic liver.

In the case, supposing the mother acquired syphilis in the early months of marriage, the contagious character of the disease disappeared in about four years. She received no treatment for her early syphilis.

Case II. Mr. B., in the summer of 1885, acquired a chancre on the lip through kissing a prostitute, and conveyed the disease to his wife, who was also treated by me. They already have several children.

On March 3, '86, a living child is born, but dies in five months from marasmus, having been puny from birth.

On May 30, '87, at full term, a macerated child is born.

On August 31, '88, a healthy child is born and remains free from the disease.

On Feb. 17, '90, a healthy child is born and so remains to the present time.

In this case the mother ceases to convey or transmit the disease in less than three years.

Parenthetically I mention that Mr. B. also conveyed the disease to his little son, two years of age, by kissing him on the forehead where there happened to be an abrasion, for it was here the chancre developed. Recovered.

Case III. Mrs. C. contracted a chancre about the time of her marriage, and was treated by me for the secondary lesions. She became pregnant for the first time in 27 months after her marriage. The child was born at full term and apparently healthy, but in about three weeks snuffles began, an eruption appeared about the anus and afterward over the body. After a long treatment it recovered.

In one year and three months after the birth of her first child she again became pregnant, went to full term and was delivered of a healthy looking child. The child is now about three months old and has shown no signs of syphilis. Neither has it received any anti-syphilitic treatment.

In this case the contagious character of syphilis disappeared *before* four years and three months—some time *after* the third year.

You may say that the child is only three months old and that it may develop syphilis later. If a child is born and does not pre-

sent evidences of syphilis before the end of the third or fourth month it is rare that it ever will. Out of 158 cases summarized by Diday only five cases presented symptoms of syphilis after the fourth month.

In brief, then, I believe that syphilis is not contagious, as a rule, after the fourth year. Exceptionally in the female it may continue until the fourth year.

2nd. What secretions contain the syphilitic virus?

None of the *physiological secretions* of the body.

Experiments by inoculation have been practiced again and again with the physiological secretions of syphilitic patients upon healthy persons without the production of the disease. Diday and others have inoculated persons with the saliva from syphilitic patients who were free from mouth lesions without results. Spermatozoa from a patient in the height of the secondary stage of syphilis have been inoculated, by Mireur, in the non-syphilitic without producing the disease. The same thing has been done with the other physiological secretions of the body and with a like result. The only elements, then, in the body that contain the germs of syphilis are the blood, and the serum which is found upon the lesions of syphilis upon the skin and mucous membranes. A man may be suffering from the secondary stage of syphilis, and providing he be free from lesions of the skin and mucous membranes, many procreate a perfectly healthy child, because he cannot inoculate the mother and a non-syphilitic mother never brings forth a syphilitic child—she cannot.

Dr. Batten: I have given a great deal of thought to this subject. The presence of the syphilitic germ depends a great deal on circumstances; upon the temperament and the constitution of the patient. In the discussion of this question we have to depend a good deal upon the truthfulness of our patients. It is impossible to watch a patient carefully; we must depend a great deal upon his veracity. Now I believe syphilis may be conveyed a long time after the patient has contracted the disease. For instance, a man has contracted syphilis in about 1869. He marries in 1882 a very plump and healthy woman, who weighed about 120 pounds. Shortly after she conceived, and gave birth to a child. Sometime during her pregnancy she took syphilis, and I treated her. The child was born healthy, but the mother was reduced to 95 pounds. She had a second child, and the second child is healthy. Both of these children are healthy, although the man's appearance denotes that he has syphilis, and denoted that before he was married.

Another case was a man whom I treated for the disease twice. He went through the usual course. He married and his wife has had three children, and they are all healthy. The wife is a healthy, fine looking woman, and well.

Another case that came under my observation was a young man who had the disease. He married and impregnated the wife, and the child was dead in the uterus. Before the next pregrancy I put her under treatment. and since that time her children have all been born healthy, and all are healthy and living at the present time. I believe, and my experience bears me out in my belief, that a person once syphilitic is always syphilitic, and that the disease may be conveyed through any of the secretions of the body.

Dr. Green: I have no criticism to offer on the paper. I believe my observations would lead me to agree with the paper. I might state an example or two that have come under my observation. One case occurs to me in reference to the length of time that the poison may remain in the system and be conveyed to others. I remember treating a young man quite a number of years ago, I think some seventeen, probably eighteen, for syphilis; he went through all the symptoms, primary and secondary. I told him not to marry for at least three years. I was not aware there would be no danger at that time, but I supposed the most dangerous period would have passed; but he married short of three years—two years and eight months. I attended his wife in confinement, but failed at any time to observe any syphilitic symptoms in the first child. I attended her in seven confinements, and I never saw healthier children than these. They are all living today. When I see them, I fail to see any symptoms in any of them; and to show you how violent an attack of syphilis this young man had, he resigned his situation and left the city and went into Maryland while the eruption was on his face. He was completely discouraged during the first year of his illness; it seemed to break his entire constitution, and I cannot tell how it happened these children are so healthy. The father of the children was killed about a year ago. About three months ago I saw the mother of the children, and according to my observation she has never shown any symptoms of syphilis. I could mention numerous instances similar to that.

Dr. Shillito: In 1883 a gentleman came to my office, who at that time expected to be

married very soon, and related this history: He told me that during the war he was a clerk in Washington City. He had contracted syphilis and had been treated by what he considered the best physicians he could find. He came to Pittsburg, and up to that time had one attack of iritis; he had also had a skin eruption. When I saw him he seemed to be a man of average health. The nasal septum was perforated. I told him after so long a time and after having received so much treatment, that there was no particular danger of transmitting it to his offspring. He married. I attended his wife in confinement, and delivered her of a living child. I think about one-third of the epidermis of the face had gone and one eye was entirely gone. The other eye was wanting until you could only see a little coloring of the cornea, and one spot that seemed to be as large as a pinhead, but since that time it admits a little light. That child enjoys good health, most excellent health, up to the present time, although of course permanently blind. I took special care to watch the mother both before and after for any marks of syphilis. I have knowledge of her ever since until up to a very short time ago, but I have not seen her within a year or two. She has had no evidence of syphilis. I understood about a month ago that she had become insane, or troublesome, and had been taken away to some asylum. They had but one child. He contracted syphilis during the war, and the child was born in September, 1884.

Dr. Thomas: What was the form of the trouble with the child?

Dr. Shillato: The epidermis of the face was nearly half gone. One eye was entirely gone and the other had just a stump.

Dr. Williams: It may be that the original trouble contracted in Washington City was not syphilis. He might have had bubo, and not had syphilis after all. There might be a suspicion that he contracted syphilis a year or two prior to his marriage, and I think it is certainly a fact that a person may contract syphilis and not have any perceivable primary lesion. I am not certain of that. I have had some experience in some of these cases, and it would certainly bear out the statement made by Dr. Thomas; and I could relate a number of instances to substantiate my position. For instance, in one case a young man had syphilitic trouble in 1883, and about the beginning of 1884 was married and his wife was delivered of a still-born child about the beginning of 1885. About 10 or 12 months after she had another still-born child. About a year after that she was delivered of a living child. About 1887 and within the past two years I have attended her twice, and her children are apparently healthy and doing fine. This was some eight years after the father contracted the disease. I am certain that if a case is properly treated the liability to convey the disease disappears after a period of three or four years. I think it depends on whether the patient has been properly treated. Unfortunately some of them are not well treated.

Dr. Lange: The matte introduced by Dr. Thomas is one upon which likely, no medical body in the world would have one opinion in almost any aspect. For instance, Dr. Batten has said that temperament, disposition or character has an influence in contracting syphilis—that a plump person with ruddy skin, blue eyes and light hair is more likely to take syphilis than a brunette. In other words, that the so-called lymphatic temperament is a predisposing cause. Now a good many members here will not agree with that opinion. It may be that a patient of lymphatic temperament will suffer more severely, but I do not agree that such an individual will take syphilis quicker or more readily than a brunette. Dr. Thomas asserts that none of the secretions are contagious if the patient, after having syphilis, presents no symptoms. I have a family in my care where the father contracted syphilis after marriage and after having two robust, healthy children, he himself being a remarkably robust, healthy man, an oil driller, and his wife being a strong, healthy woman. This man had two children when he contracted syphilis. He had treatment for three years, and at the end of that time presented no symptoms. Then he had two additional children born without symptoms; one of these is now about five years and the other about three. They have presented no symptoms of syphilis. Now he has a child 18 months old, which is syphilitic very distinctly. It may not be fair to say with some members here that once syphilitic always syphilitic, but it is certainly remarkable that towards the end of life syphilitics who presented no symptoms for many years, again have this disease reassert itself, and often such reassertion ends life. This comes as aneurism, apoplexy, atheroma, aud as connective tissue hyperplasias of the brain, the liver, the cord, etc.

Dr. Barclay: My impression is, from what I have seen, that syphilis, after the secondary stage, is possibly not contagious, although I am not certain about that. It is not advisable for persons who have had

syphilis to marry short of three years after syphilitic manifestations have disappeared; that has been my rule, to advise persons who have had syphilis not to marry short of three years after all manifestations have disappeared. I have said to them with a good deal of confidence that I thought it would be safe after that to marry. I saw recently a young girl who was poisoned by a dentist. The dentist who extracted her tooth abraded her lip. I saw her three weeks afterwards, and my opinion was, after I examined her, that she had been poisoned. I was careful not to give her a positive opinion, but advised her to see other physicians. They were of like opinion, advising me to watch the patient for manifestations. The secondary manifestations came on in about sixty days afterwards, and there is no question she was poisoned in that way. She said the dentist hurt her lip at the time he extracted her tooth. To me it was a very interesting case. I have treated her since and her hair has dropped out. This case was referred to a lawyer, and in all probability there will be a case in court. I have placed myself in a position of security by having her see other physicians; three or four other physicians have examined her, so if it comes into court the profession may be protected.

Dr. Buchanan: I have nothing to say on the subject introduced by Dr. Thomas, but I have a word to say about the case which was reported in which a dentist is charged with having introduced syphilis by means of his instruments. We all know the variety of ways by which an abrasion of the lip can be made. I think if this case should come into court, the plaintiff would have the very greatest difficulty to prove that the abrasion on the lips was the site of the chancre, showing that the inoculation was made by the instrument that produced the abrasion. Suppose this girl had a family friend who had something on her lip, and that she kissed her friend good-bye at a station about the time when she received the injury at the dentist's, she would have received this inoculation, and the dentist would have to bear the blame. This girl might have received the inoculation by a drinking cup, she might have wiped her face with a towel that the servant girl had used, she might have received it in a thousand ways, and still this dentist must bear the blame. I think, as we use the instruments ourselves, we should be exceedingly careful of implicating in any way any member of the cognate profession of dentistry.

Dr. Barclay. I appreciate what Dr. Buchanan has said, and I have been just as careful as he could be. It seemed to me from the history of the case that she was certainly poisoned by the instrument. I know and appreciate just as highly as any one could, how much danger there is to the dental profession and the medical profession from this very cause, and I very carefully looked into that matter, and I am well satisfied when I say I believe she was poisoned by a dentist's instrument. The history of the case goes to prove very clearly that the lip became indurated the third day, that there was a large lump in her lip and the glands were sore. Of course what Dr. Buchanan said is true: she may have kissed a friend. I inquired as to that and I am satisfied if she was poisoned by any other means except the one referred to, she was innocent of knowledge of it.

Dr. Buchanan: According to this statement, the chancre appeared on the third or fourth day after the inoculation. We all know that is entirely too short a time. We know if we inoculate a person with syphilis it never appears on the third or fourth day; it takes a good while longer. If it appeared on the third or fourth day after the dentist extracted the tooth, then he did not inoculate her.

Dr. Barclay: Morton, in a recent work, states it may make its appearance on the first up the seventieth day.

Dr. Davis: I would like to ask the society if any one has known a case of syphilis to be communicated after the third year to their children, or any one else; that he can say of his own experience syphilis has been communicated after the third year.

Dr. Williams: I have in my charge a man who was married seven years ago, who had an eruption on his body. He had a chancre, but did not give it any attention. About six month after the manifestation of syphilis, after the rash manifested itself, he married, and in due time a rash of similar kind came over the wife. He was then taking anti-syphilitic treatment. I do not remember the exact year, I think three years after his marriage, his wife was delivered of a child, and unlike the cases reported by Dr. Thomas, there was a manifestation of syphilis on the skin, entirely covering the child. The child died in about three weeks. Four years after this the man was presented with another member of the family, and a like condition exactly was manifested in the child.

During this time he was taking anti-syphilitic treatment.

Dr. Lange: I stated a case a little while ago and forgot to say that during the time these three children were conceived and born

the mother had not at any time any manifestations of syphilis; never at any time. Two of the children are healthy, the last one syphilitic, and the mother at no time presented syphilis.

Dr. Davis: Do you know whether she could have taken syphilis?

Dr. Lange: She never had symptoms.

Dr. Green: Can you exclude all evidence of a nurse or some of the attendents not conveying it to the child. I have seen a number of instances myself where the mother and father were clear, yet the child was syphilitic.

Dr. Lange: These children were fed with bottles, in the hope that if taken away from the mother it would lessen danger in the first two, and the third child was nursed.

Dr. McKibben: On the 2d of August I delivered a woman whose husband was treated for syphilis about six months, when he got careless and stopped treatment. After three months he had mucous patches in the mouth, for which I treated him. He was anxious to get married. I told him it would not be advisable, but after a period of about eighteen months he married; his wife became pregnant, and the child was born on the 2d of August, perfectly healthy, and the mother has not shown any symptoms.

Dr. Shaw: I have in mind four men who had syphilis before marriage. Three of them had it severe enough to warrant a visit to the Hot Springs. They have all married, all have children and none of the children have ever shown any manifestation of syphilis. I cannot give the exact time in any one case, but an interval of at least three years from the time of the first manifestation of the disease elapsed before the marriage took place.

SELECTED FORMULÆ.

A LOCAL ANÆSTHETIC.

Struver recommends the following:

℞
Cocaine.....grammes 5.
Antipyrin..... " 15.
Distilled water..... " 80.

—*L'Union Médicale.*

TREATMENT OF TYPHOID FEVER.

A good authority in Paris recommends the following treatment for typhoid fever:

℞
Salicylate of bismuth.....grs. x.
Naphthol A.....grs. viij.
For one wafer, night and morning.

Sulphate of quinine.....grs. xx.
Extract of cinchona.....3 j.
Decoction of valerian.....3 iv.
To be administered by the rectum at four in the afternoon each day. Besides which, three enemas of cold water during the day. Bordeaux wine and beef-tea.

PAPOID IN DIPHTHERIA.

℞
Papoid.....gr. x.
Aquæ.....3 ss.
M. f. solution.

Kohts and Asch painted diphtheritic membranes with this solution every fifteen or twenty minutes with a soft brush. They found that the oftener the application was made the more rapidly membranes disappeared. Kohts treated several hundred cases by this method with the greatest success.

℞
Papoid.....5 ij.
Beta-naphthol.....gr. iij.
Acid hydrochl. dil.....gtt. xv.
Aq. destil. ad.....3 iv.
M. ft. solution. Sig. Use carefully and thoroughly by means of hand atomizer every half hour on throat and through nostrils on posterior nares and pharynx, if deposit extends to these localities. Papoid solutions should be made fresh.

TREATMENT OF ACUTE GONORRHŒIC ORCHI-EPIDIDYMITIS.

Dr. W. Parker (*La Semaine Médicale*, No. 55, 1891) recommends the following:

℞
Argent. nitrat.....grammes 4.
Ether nitros. alcoholizat..... " 30.
For external use. This is painted, with a stiff brush, on the testicle attacked, once a day for two consecutive days.

Then he employs the following:

℞
Laudani..... } āā grammes 40.
Plumbi subacetat. liquid..... }
Aq. destillat..... " 440.
For external use. Apply a compress to the testicle, which is kept constantly soaked in this solution.

The effects of this treatment are said to be excellent. The pain and inflammation rapidly disappear.

EXPECTORANTS.

The *Lancet-Clinic* says that Dr. Rossbach (*Ugeskrift for Læger*) praises the following:

℞
Morphiæ hydrochlorat.....gr. ss.
Apomorphiæ hydrochlorat.....gr. ss to j.
Acid. hydrochloric. dilut.....gtts. x.
Aq. destillat.....3 v.
M. Sig. A spoonful every second to fourth hour.

We have found the following efficient at times:

℞
Tinct. opii camphorat,
Syr. pruni Virg.,
Fl. ext. glycirrhizæ,
Spts. frumenti.....āā 3 j.
M. Sig. A teaspoonful every hour.

RECURRENT TONSILLITIS AND PERITONSILLITIS.

Dr. Tori (*La Rivista clinica e Terapeutica*, No. 10, 1891) employs the following:

℞
Iodii metallic,..... .....centigrammes 10–30.
Potas. iod., }
Tannin, } .....āā grammes 1–3.
Aquæ..... " 100.
Use as a gargle two or three times daily.

If this be used faithfully for three months the patients will be permanently, or for years, relieved of their recurrent attacks of tonsillitis.

LEADING ARTICLE.

THE EFFECTS OF LA GRIPPE UPON THE MIND AND NERVOUS SYSTEM.

The degree to which epidemic influenza disturbs the nervous system varies very much in different epidemics. Although this is affirmed by many prominent clinical observers, no one as yet has satisfactorily explained why this is so. It may be safely said, however, that, apart from atmospheric conditions favoring the development of the specific poison, the chief reason is, most probably, in the general constitutional conditions of the affected community. Thus, among a class of persons prepared by heredity, mode of life, or special predisposing causes to have some form of nervous or mental disease, we can readily imagine how an ordinary epidemic of influenza would prove in this community largely productive of nervous or mental troubles.

Among all classes influenza is quite commonly complicated with or followed by symptoms indicative of disturbance of the nervous system. Everyone is familiar with the severe frontal headache, the torturing back-ache, lancinating pains in the limbs, the throbbing local eye-pains, and also the nerve-exhaustion, insomnia, various hyperæsthesiæ, vertigo, supra-orbital neuralgia, stupor, convulsions in children, and even graver nervous symptoms.

An excellent paper entitled "Nervous and Mental Complications of La Grippe" has recently been read before the Academy of Medicine by Phillip Zenner, A.M., M.D., of Cincinnati, in which he reviews the more common nervous troubles above referred to, and also reports some very interesting cases. One of these was that of a woman, aged 52 years, who had an ascending paresis deepening into paralysis, which commenced with numbness in the toes two or three months after her attack of influenza, and gradually ascended to the lumbar region, when the hand and arms also became affected. Sensation and muscular sense were impaired. She died in about one year of exhaustion and

bedsores. The writer inclines to the belief that the case was one of myelitis and not a multiple neuritis. It will occur to anyone that possibly the attack of influenza should not be held directly responsible for such symptoms as this case presented, when several months elapsed prior to the development of the trouble. The same author reports in the same paper three cases of mental confusion with abnormal fears and irritability, a borderline case of insanity, and a case of acute delirious mania attended by labial tremors and sluggish movements of the iris to light, but ending in recovery in one year. The symptoms in the later case directly followed influenza.

Thus *grave nervous maladies* may complicate or follow epidemic influenza. We cannot attempt more than to briefly indicate the varieties of nervous affections which have been reported during the past two years. For the sake of convenience these may be divided into the following groups:

I. Functional nervous disturbances, including nervous troubles of almost every organ of the body, and hysterical affections.

II. Inflammatory diseases of the nervous system, including meningitis, cerebral or spinal; polio-myelitis, optic neuritis, peripheral and multiple neuritis.

III. Systemic nervous affections, such as neurasthenia, glycosuria, exophthalmic goitre, epilepsy, chorea, etc.

IV. Paralytic affections, including aphasia, hemiplegia, ocular paralyses, optic atrophy, ascending palsy, etc.

V. Insanity, which, judging from reported cases, may take any of its various forms.

The purely nervous diseases having already been referred to, the last class of cases may properly be considered briefly. There is now no doubt concerning the power of influenza to induce an attack of insanity in a predisposed person, and many go further and say that it may be the only cause of the attack. The mental affection may occur at the very beginning of the attack of influenza, may arise as a complication during the stadium of the disease, or may appear as a sequel. Dr. Authur H. Harrington, of Danvers, Mass., has contributed a valuable paper bearing upon this subject, which he read at the Annual Meeting of the Massachusetts Medical Society, June 10th, 1890. His paper is based upon twelve cases occurring in the Danvers' Asylum, together with thirty-six cases collected from the insane hospitals. In thirty-one of these cases grip acted as an exciting cause, but other causes were also presented in their histories. In the remaining seventeen cases, influenza was the sole assignable cause. Of the whole number thirty-three per cent. recovered. Harrington considers from a study of these cases that while any of the common types of mental disease may follow influenza, acute confusional insanity is most common. He also publishes in his papers replies from his circular letter of inquiry to various hospitals, as follows:—From Dr. Cowles, of the McLean Asylum, "I do not know that the mental symptoms have presented any noticeable peculiarity except the tendency to prompt recovery as if upon the abatement of some debilitating or depressing iufluences;" from Dr. C. M. Hay, of the State Hospital at Morris Plains, N. J., "Generally the insanities in these cases have been of a very marked type, but whether this was due simply to the exhaustion in which the mental affection found them, or was connected with a specific toxæmia I cannot say."

Some cases have been reported in which influenza exercised a favorable, or even curative, influence upon insane patients, but we think that its beneficent effects have been largely exaggerated. No doubt it has modified many cases of insanity in the same manner that any severe illness may modify mental symptoms, or even such disturbances as the epileptic convulsion. Many instances are known to us in which epileptic cases, having usually two or three fits a day, would not have a single convulsion during a prolonged illness, both medical and surgical in character.

Concerning this alleged tendency of grip to cure insanity, Dr. Lyon, the present Super-

intendent of Bloomingdale Asylum, says, "I have seen no such remarkable cures from chronic insanity, or any other form, effected by the 'Grippe,' as I have read of;" and Dr. Park, of the Worcester Hospital, says, "We have had no cases of recovery from chronic mania due to 'Grippe.'" We cannot but think this error in observation is responsible for these reported cures of insanity by influenza. Metz (*Neurolog. Centralblatt*, 1890) reports a case of paranoia cured completely, and Helweg (*loc. cit.*) adds two cases of dementia, one improved and one cured. Helwez also advocates the use of antifebrin to favorably influence the nervous and mental complications of grip.

What conclusions may be drawn from the wide array of nervous and mental symptoms which confront us in the current literature concerning epidemic influenza? Although we may wisely make allowance for an element of exaggeration of its etiological importance, no one can go over the subject without being impressed that influenza does cause widespread disease of the nervous system, and also has the power to derange that highest expression of organic life, the Mind itself; and we must conclude that it does so by disturbing, in some manner at present only to be conjectured, its physical basis—the brain. There is nothing strange in these effects of influenza. We note many nervous troubles arising from other infectious diseases, as, for example, typhoid fever, diphtheria, and malaria.

The practical point to bear in mind concerning this whole subject is its etiological importance, especially as it bears upon prognosis. Although nothing very definite may be stated at present, the indications are that all nervous and mental troubles arising directly or indirectly from epidemic influenza have a more favorable prognosis than if arising from other causes, or idiopathically. This is especially true of all functional nervous and mental troubles, and in the latter cases even some physical symptoms of brain disease may be of much less fatal import when they occur in the psychoses due to grip.

While, in our opinion, influenza should not be introduced into the nomenclature of nervous and mental troubles (as has been already attempted), still it is of the utmost importance to give due weight to its causative influence, as shown in the reported testimony, bearing in mind that it shares the power of producing all of these grave neuropathic disturbances with other infectious diseases.

BOOK REVIEWS.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. Galliard Thomas, M. D., LL.D., Emeritus Professor of Diseases of Women in the College of Physicians and Surgeons, New York, and Paul F. Mundé, M. D., Professor of Gynæcology in the New York Polyclinic. New (sixth) edition, thoroughly revised and rewritten by Dr. Mundé. Large 8vo., pp. 824, with 347 illustrations. Philadelphia: Lea Brothers & Co, 1891. Price, cloth, $5.00; leather, $6.00.

This new edition of Dr. Thomas' work will be received with more than usual interest because of the solid merit of previous editions and of the popularity which they enjoyed for many years. To bring out a new edition of a work on gynæcology ten years old, during which time the subject has been marvellously progressive, is no mean task, and at the same time to try to preserve the peculiar and characteristic features of the work, is a very difficult task indeed. On the whole, we feel that Dr. Mundé has done his work well, and the book will continue to be one of the standard text-books of the day. Nevertheless, we feel that further alterations, omissions and substitutions would have brought the work more in touch with the current thought. This criticism applies, however, to most text-books, especially to those on subjects in which rapid progress is being made.

It is assumed by authors that relatively new theories or modes of practice should not be considered in a text-book for fear that further experience should prove their fallacy, while they ignore the fact that much which they present is obsolete or obsolescent. We feel that this distinctly detracts from the value of all text-books, especially those on gynæcology. It might be well to put obsolescent matter and new matter in smaller type, but certainly if one is retained the other should be produced.

The peculiar and good features of this book are so well known that it is scarcely necessary to refer to them here. It is pleasant to note many improvements in this edition. The

illustrations are distinctly better and more profuse. New chapters on Electricity, Hermaphrodism, Diseases of the Urethra and Bladder, and Diseases of the Female Breast have been added.

It is interesting to find that although Dr. Mundé was one of the first to use electricity for the diseases of women, his estimate of its value is a very moderate one. It is equally gratifying to find that so careful a man is convinced that it has positive value in the treatment of chronic inflammatory conditions (when pus or retained secretions are not present), and of neuralgias and of uterine fibroids; that its action on morbid conditions within the pelvis is quite similar to that in other portions of the body.

The chapter on the perinæum and its injuries and their results is most elaborate and carefully written, and is an able presentation of the author's views upon the subject. Those, however, who have been convinced by the teachings of Emmet, that the old theory concerning the perineal body so-called is wrong, will not agree with many of the author's views. It is lamentable, also, that so inadequate a presentation of Emmet's views upon the functions of the pelvic floor, and the nature of lacerations thereof, and the proper method of their repair, should be given. In criticising this operation of Emmet's, the author says that it is a perfect operation for rectocele, but leaves the vulvar orifice gaping, and is, therefore, defective. In this opinion he differs from Noble, Kelly, Price and others having large experience with it, and who have had only perfect results.

The illustration of "Emmet's new operation for lacerated perinæum," (p. 205,) is absolutely incorrect. With sutures introduced as there figured the result would be that stated by the author—but the operation figured is not Emmet's.

Dr. Thomas somewhat extensively treats of subinvolution of the vagina and of the perinæum (p. 167), describing the physical conditions which are recognized by others to be due to submucous laceration, or overstretching of the levator ani muscles and the perinæal fascia. He claims priority in calling attention to the subject. It would seem that his claim rests upon a determination of the real nature of the conditions present.

The alterations in the chapters on Pelvic Peritonitis and Pelvic Cellulitis are extremely slight. This is also true of Hæmatocele and Ectopic pregnancy. Much of the matter on Pelvic Cellulitis should have been transferred to the chapter on the History of Gynæcology. The chapter of Diseases of the Fallopian Tubes shows that Dr. Mundé appreciates the remarkable progress which has been made in our conception of pelvic inflammation and its treatment within the past ten years, but he clings to the old pathology which has been largely disproved and displaced.

The work of the publishers is in every way satisfactory: paper, printing and illustrations being unusually good.

ESSENTIALS OF PHYSICS, ARRANGED IN THE FORM OF QUESTIONS AND ANSWERS, PREPARED ESPECIALLY FOR STUDENTS OF MEDICINE, by Fred. J. Brockway, M. D., Assistant Demonstrator of Anatomy at the College of Physicians and Surgeons, New York, with 155 illustrations. W. B. Saunders, publisher, (Phila) 1892. Price,$1.00

Saunders' Question Compends are already notable for their uniform excellence, and the present number is no exception to the rule. The author has endeavored to compile a work which would embrace what the student of medicine should know of the subject, and in this he has been very successful. As a whole, the Compend is most excellent.

SURGICAL ANATOMY FOR STUDENTS. By A. Marmaduke Sheild, M. B., (Cantab) F. R. C. S., Senior Assistant Surgeon, Aural Surgeon and Teacher of Operative Surgery, Charing Cross Hospital. D. Appleton & Co., New York. 1891.

A careful reading will convince any one of the value of this little book of 200 pages, which covers in a very complete manner the field of practical surgery. The subject is dealt with in a very direct and practical manner, and it will prove a useful, handy reference book for practitioners. For teaching purposes, if used in connection with the cadaver, it will probably be found very advantageous to the student.

It is issued in an attractive and convenient binding, with very readable print. A liberal use of explanatory headings, and heavy type for the sake of emphasis to certain most important parts would have added something to the book. The same may be said of the introduction of diagrams and wood-cuts to illustrate important parts. However, we already possess such a list of well-executed drawings for the student that their absence in this book is a sort of relief, and an advantage to the book perhaps, for its chief value is in its admirable arrangement, and its use of plain, explicit directions, entirely suitable to the student-mind.

As a contribution solely adapted for the surgical anatomist—the purpose for which it was prepared—we can heartily recommend it.

LITERARY NOTES.

Mrs. Humphrey Ward's new novel, "The History of David Grieve," has proved so great a success that the publishers have decided to issue at once an edition in larger type, in two volumes, uniform in size and style, with the Eversley Edition of Charles Kingsley's works. The new edition will be printed by Berwick & Smith, in Boston, and will be ready before the end of the month.

Apropos of the eighty-third birthday of President Lincoln, *Harper's Weekly* for February 13th contains a superbly illustrated article by Charles Carleton Coffin on the "Ancestry and Early Years of Abraham Lincoln." The illustrations, which are numerous, include views of the localities made famous as the scenes of Lincoln's childhood and youth, as they now appear, and the portrait is from the first ever taken of the President. Of this picture Mr. Coffin says: "It was taken in 1857 in Chicago. Lincoln was visiting his niece, Mrs. Harriet Chapman, in Charleston.

"'Uncle Abe,' she said, 'I want your picture.'

"'Hattie, I never had it taken, but I am going to Chicago in a few days, and will sit for you," he replied.

"A few days later the picture was received by Mrs. Chapman. I obtained this copy in Charleston, Illinois, October, 1890, and received the above information from Mr. W. G. Chapman."

Sir Edwin Arnold, who has been enjoying an interesting trip through the United States, has made a careful study of the conditions which govern the family in Japan and embodies his ideas in a paper called "Love and Marriage in Japan," in the February number of *The Cosmopolitan*. The article is illustrated by the quaintest possible Japanese sketches, running down the sides and across the bottom of each page. An excellent photograph of W. D. Howells serves as a frontispiece, and his work as a writer of fiction is reviewed in the same number by H. H. Boyesen. The President of Johns Hopkins University gives a most practical paper for parents on "Boys and Boys' Schools," illustrated by cartoons of the famous Attwood. Murat Halstead turns back lovingly to his early farm days, and tells of the "Pets and Sports of a Farmer Boy." The petroleum industry is fully illustrated; An Afghan Story by Archibald Forbes; The Story of the Brazilian Republic, by Adams, late Minister to that country, and The Leading Amateurs of the United States in Photography, are other leading articles of the month.

THE PHYSICAL TRAINING OF BOYS.

Boys of to-day have great advantages in their physical training over those of even ten years ago. It is easily within the remembrance of those of us who have not been out of college so very long, how the mere mention of football at home brought down a storm of parental wrath, while unrelenting prohibition followed us back to school. The game was then an enigma, and the newspapers added horror to the mystery by printing their accounts of matches in a manner calculated to chill the blood of any well-regulated household.

Gradually as the sons induced their parents to view the sport themselves, the prejudice wore away. The game finds favor in schools from Maine to California, and the result is a generation of lads growing up whose physical beauty and healthful condition put us of the last generation to shame. Our very sixteen-year-old stripling can outrow, outrun, outswim, outride and outdrive us; give us points on foot-ball, base-ball and tennis; and happily devoid of that sickly pallor peculiar to the student of our day, knows quite as much, with the ruddy glow of health in his cheeks. And yet there are to be found some few that do not favor athletics for boys!! The glorious influence for good that sports have on the general education and welfare of both boys and girls has not begun to be appreciated. When I see a boy who does not take his play-hour, I regard him with as much disquiet as the man who never has a kind word for any one. Play is as necessary to the boys and girls as water is to a plant. Without it the growth of the one is restricted and unhealthful, while the other, having fewer resources, dies. — From *Harper's Weekly.*

COUPARD'S TREATMENT FOR CORYZA.

Dr. Coupard publishes in the *Monde Therapeutique* the following formula for a snuff which has been for a long time very successful in the treatment of coryza:

℞ Cocaine hydrochlorate.....cgm. 15.
Menthol..... " 25.
Boric acid..... gm. 2.
Coffee, parched and finely pulverized....cgm. 50.
Mix. Sig. Take five or six good pinches, as a snuff, a half dozen times daily.

CORRESPONDENCE.

ARE COLDS CONTAGIOUS?

EDITOR MEDICAL AND SURGICAL REPORTER:—Alluding to an article "Are Colds Contagious?" quoted in the REPORTER from the *Medical Press*, I would offer the following. Like all true Buffalonians I have been very subject to nasal and pharyngeal colds, but for the last two years, following the advice of the late Dr. Frank H. Potter of this city, I have used for myself and others a spray of menthol in liquid cosmoline as soon as the first symptoms of coryza have appeared. This treatment has, with few exceptions, aborted the colds.

Unless menthol has some mysterious virtues aside from its well known antiseptic and carminative action, a very natural reasoning from effect to cause would lead to the conclusion that the colds thus treated were of bacterial origin. This theory is corroborated by observing the little "epidemics" of coryza which frequently occur. But why should we expect to find a specific micro-organism any more than in the case of septicæmia, which may depend on one or several of quite a variety of bacteria?

THERAPEUTICS.

WARM ETHER AS AN ANÆSTHETIC.

We learn from the *Independencia Medica*, of Barcelona, that on October 31st Dr. Giné y Partagás performed an operation for osteoma of the fibula of a woman, in the Hospital de Santa Cruz of that city, the anæsthetic used being ether warmed to 31° C., which was administered by Dr. A. Diaz de Liaño, with an apparatus of his own invention. Anæsthesia was rapidly induced, and was kept up for fifty-five minutes without any accident. The temperature of the ether remained at 31° nearly to the end, when it fell to 29.5°. The apparatus, which is called by its inventor an "Electro-thermo-etherizer," has since been used in several other cases with equally satisfactory results, anæsthesia having on one occasion been kept up two hours and a half without any ill effect. Dr. Diaz de Liaño claims that by his method the disadvantages both of cold ether and of chloroform are obviated. Our contemporary promises a full description of the apparatus at an early date. —*Brit. Med. Jour.*

TREATMENT OF INFLUENZA.

Dr. Francis Delafield stated at the meeting of the Medical Society of the County of New York, on Monday, January 25th, 1892, during a discussion on the epidemic of Influenza, that his treatment of influenza consisted of putting the patient to bed and seeing that he was well nursed and had proper diet while the disease was running its course. It was possible, however, for the physician to interfere with advantage in the case of certain complications. Of all the remedies suggested for the treatment of influenza and its complications, such as severe headache and neuralgia pains, etc., he had found nothing so reliable as phenacetine, in doses of five grains every two hours. The catarrhal throat trouble, which is often present, he had treated successfully with aconite or salicylate of soda, with a solution of cocaine for local applications.

TREATMENT OF BRONCHO-PNEUMONIA IN CHILDREN BY SUBCUTANEOUS INJECTIONS OF THE HYDROCHLORATE OF QUININE.

In the *Journal de Médicene de Paris*, June 21, 1891, Dr. St.-Philippe calls attention to the difficulty in diagnosis between pneumonia complicated with enteritis and typhoid fever, while from the point of view of treatment he points out that there are two features which are valuable indications as to the methods to be pursued. First, as to the degree of bronchitis; and second, as to the extent of the pulmonary lesion, for the congestive process may be so sudden and expensive as to produce death in a few hours. Against this latter form of danger Dr. St.-Philippe maintains that there is no drug which can equal quinine, whether administered by the mouth, the rectum, or under the skin. Sulphate of quinine he gives in black coffee, while in very small children of those who refuse to take medicine it may be employed in enemata or powders; but both these modes of medication are slow in action, and for entire reliability he usually recommends the employment of quinine in subcutaneous injections, making use of a solution of chlorhydrate of quinine and equal parts of glycerin and water. Quinine thus forms his main reliance in the treatment of broncho-pneumonia, to which may be added blisters, which he even allows to pass on to suppuration over the localities where râles are most abundant. In suffocative catarrh he has recourse to mustard plasters, large blisters or leeches, according to

the age of the child; while in some cases he employes tincture of aconite root in doses of 5 to 20 drops in twenty-four hours, and in syrup of aconite in cases where the bronchitis is intense, while quinine and punch are given when the general state is at all depressed. In states of excitement he does not advise the use of opium, but warm baths and small doses of antipyrin. In severe cases, quinine and aconite are to be abandoned, and caffeine given subcutaneously, and reliance placed upon digitalis and alcohol as stimulants. He likewise states that oxygen inhalations have given better results than injections of ether. —*Therapeutic Gazette.*

When administering chloroform note the action of the heart, but watch the respiration especially.

CAMPHORATED SALOL IN DISEASES OF THE MIDDLE EAR.

Dr. Pégon has recently reported in the *Revue de thérapeutique* some very favorable experiences with camphorated salol in the treatment of suppurative disease of the middle ear. The formula for the preparation, devised by M. Desesquelles, is as follows: Equal parts of salol and camphor are mixed and heated until fusion is complete, without water, alcohol, or any other solvent. The mixture is then filtered and preserved in a yellow glass bottle hermetically sealed. Thus prepared, camphorated salol is a thick, colorless, unctuous liquid, soluble in ether, chloroform, or oil, but insoluble in water. Light and air decompose it rapidly. Its application is neither painful nor irritating, and it seems to possess the property of rapidly curing a distressing and very intractable disease. It is applied upon a small pledget or tampon of cotton-wool; to this may be attached a fine thread by which the patient can remove it after twenty-four hours. The ear should previously be washed out with a weak boric-acid solution, and the washing should be repeated once or twice daily when the tampon is not in position. The applications are made once in two or three days, and, if the suppuration is not profuse, the tampons may be left *in situ* from one application to another. The time required for a cure varies from four to twenty days. Dr. Pégon has found the method to succeed where the more popular ones have failed, and says that even where it has not made a perfect cure it has always diminished the fœtor and amount of the purulent discharge.

TREATMENT OF HEADACHE.

Dr. C. W. Suckling of Birmingham (*Birm. Med. Rev.*), after dealing with the varieties of headache, directs attention to the indications for treatment in migraine. Care must be taken to place the patient in the intervals of the attacks under favorable conditions. Tobacco, alcohol, and especially mental worry, must be forbidden; hot and crowded rooms must be shunned; errors of refraction should be corrected, and the patient's diet strictly regulated. A pill twice daily continuously consisting of one-sixth of a grain of the extract of Indian hemp, one-tenth of a grain of phosphide of zinc, and one-thirtieth of a grain of arsenic may often give great relief. The severity and number of the attacks is often effectually diminished by one minim of liquor trinitrinæ two or three times daily after meals, continuously. For the actual attacks, rest in bed in a dark room may be necessary; and relief may be secured by a draught every hour consisting of ten grains each of antipyrin and ammonium bromide with twenty minims of sal volatile. The dyspeptic headache is usually removed by blue pill and euonymin.—*Practitioner.*

When alcohol and water are mixed the combined volume is less than the sum of the two liquorsseparate.

THE ACTION OF OREXIN ON THE STOMACH.

Dr. W. Brunner, in *Gazette Lekarska*, March 14, 1891, gives his experience with the use of orexin, and its action upon the stomach.

His experiments were made upon 30 persons (180 separate observations). The doses employed were 0.25 to 0.30 gramme, in pills or capsules, two or three times daily.

In four healthy persons pain in the epigastrium and vomiting appeared after the second dose was taken.

In twelve neurasthenic and hysterical patients, with impaired mechanical action of the stomach, the appetite was increased in six; this did not last long, for upon stopping the use of the drug, the appetite became poorer than before, with pain in the stomach and severe ringing in the ears. In another group of 10 cases (patients with consumption, rheumatism and cardiac disease) the effect was also doubtful. In four cases of gastric diseases (1 catarrh, 2 cancer and 1 dilatation), the pain and vomiting were aggravated.

In view of these experiments, the author recommends that orexin be dropped entirely from the list of reliable medicinal remedies.

TO HASTEN DESQUAMATION IN SCARLATINA.

Dr. Jamieson (*Norsk Mag. for Lægevidenskaben*, No. 11, 1891), has employed 30 per cent. of carbolic acid in oil with good results; but resorcine has served him better. This latter is combined with salicylic acid and employed in the form of a superfatted soap. The patients are anointed with this when desquamation begins; after this the skin is rubbed with some indifferent fatty substance. The nurse should wear rubber gloves to protect her hands. With these means the writer has shortened the period of desquamation 55.5 to 40.26 days.

THE NEW TREATMENT OF CARCINOMA.

New methods of treatment designed for the cure of malignant disease are so frequently being brought under the notice of the profession that we feel some apology is due for referring to some facts in connection with this subject which have been supplied to us by our Vienna correspondent. A few months ago Professor Adamkiewicz announced that by means of some experiments he had been able to arrive at a certain method for curing cancer. The excitement which this announcement made in Vienna was such that the Minister of Education was induced to invite the Professor to come to the Austrian metropolis for the purpose of testing his new treatment in one of the State hospitals. In a ward under the charge of Professor Billroth, Adamkiewicz was permitted to experiment upon a patient who was believed to be affected with epithelioma of the upper and lower lids of the right eye. The history showed that the disease was rapidly spreading, and, under the circumstances, therefore, the case seemed a most suitable one for testing the value of the new treatment. On October 25th the Professor took the patient in hand, the result being that on November 12th the sufferer was discharged from the hospital—cured. In other words, after eighteen days' treatment an epithelioma of the upper and lower lids was pronounced by Adamkiewicz to have perfectly cicatrized over. Naturally enough on this matter Professor Billroth had something to say, and what he has said can scarcely be deemed to be enthusiastically favorable to this latest form of cancer curing. Billroth remarked that he had no doubt about the case being one of epithelioma. It was true also that the growth had cicatrized at the centre and in the periphery. But whether it was a growth possessing distinctly malignant characters was open to some doubt. No signs of secondary infection had been noticed, nor was there any enlargement of the nearest lymphatics. Again, it had repeatedly cicatrized after treatment by caustics and "scrapings." Moreover, if the centre only of the growth were scraped, leaving a bleeding surface, healing would take place there, while at the periphery the disease would continue to extend. Upon the whole, then, Billroth contended that Adamkiewicz's treatment had accomplished nothing, and that our knowledge of the subject of the treatment of cancer had not been in any way advanced by these experiments. Professor Kaposi admitted that he had treated the same patient fifteen years ago for the same kind of growth, and obtained a successful result by the application of caustic. He quite agreed with Billroth in the belief that the epithelioma was not a malignant formation in the usual acceptation of the term. He expressed a wish to know how Adamkiewicz performed his experiments—whether the injections were made locally or otherwise. Still more condemnatory of the new treatment were the remarks of Dr. Franks, who spoke on behalf of Professor Albert. According to the latter observer, the experiments conducted in his clinic by Professor Adamkiewicz appeared to have very little influence over the new growths, and he believed that massage or any other mechanical irritation would have the same effect in reducing the size of the tumors. There was nothing, in his opinion, in the new treatment which could be considered of any real value. Thus has this last new method of curing cancer been finally disposed of. We referred to the matter at length in our issue of August 5th in our Austrian correspondence, and from the cases which Professor Adamkiewicz had then recorded it was naturally thought that his method should be submitted to a crucial test. This test has now been applied, with a result which leaves no possible reason for doubting that the treatment in perfectly valueless for the purpose for which it was introduced.—*Med. Press.*

GLYCERIN FOR BURNS.

M. Grigoresen, of Bucharest, highly recommends pure glycerin as a remedy for burns. On first application a slight burning feeling is experienced which soon gives away to a local anæsthesia, somewhat resembling that produced by carbolic acid. In severe cases, two or three applications should be made, so that the parts are kept wet constantly with glycerin. Under this treatment the inflammation is subdued almost completely, and only a slight cicatrix is usually left.

MEDICINE.

TYPHOID FEVER AND INSANITY.

M. Joffroy reported four cases of interest. The first was that of an old woman who had typhoid fever at the age of 33, with nervous troubles and delusions during convalescence. In the second case the patient had been subject to attacks of hysteria formerly; occasional delusions during attacks of typhoid, some of which persisted, Third case was one of typhoid fever, followed by dementia. Fourth case was one of paraplegia preceded by typhoid fever, which appeared to exist in a latent state. M. Weill thought that typhoid fever poison was no more powerful in producing insanity than that of any other infectious diseases. To this view M Joffroy dissented.—Report of Congress in *Le Prog. Méd.*

"CÆCITAS SYLLABARIS ET VERBALIS, SED NON LITTERALIS."

Under this title Professor Ivan P. Mierzejewski, of St. Petersburg, describes (*Vestnik Klinitcpeskoi ï Südebnoi Psïkhïatrïi ï Nevropatologïi*, vol. ii, 1891, p. 26) a case of peculiar word blindness with normal letter vision. The patient was very nervous, emaciated, pale, and weakly-built medical man, aged 56, suffering from pronounced sclerosis of the temporal vessels, pulmonary emphysema, cardiac hypertrophy, chronic bronchitis, and chronic nephritis. When 23 years of age he had had syphilis. In January, 1890, he suffered from dropsy and uræmic drowsiness of four or five days' duration. The latter condition subsequently recurred twice at intervals of about two months. Shortly after the third attack of somnolence the patient noticed that he was unable to read, though he could distinctly differentiate letters, and his sight was otherwise good. At present examination shows that he actually can differentiate every individual letter, but utterly fails to combine letters into syllables or words. He can write to dictation freely and correctly, but is unable to read what he has writlten, Similarly he writes his prescriptions correctly, but is unable to verify their composition. He can copy anything perfectly well, but without understanding either the original text or the transcript. Meanwhile, he reads and understands figures, being able to name correctly even numbers of many figures. His sight is excellent, the ocular fundus absolutely healthy, speech distinct and generally normal, his mental faculties unimpaired, and there is nothing abnormal about his motor, reflex, or sensory functions.—*British Medical Journal.*

FACIAL HEMIATROPHY.

The *Neurologisches Centralblatt*, No. 15, 1891, contains abstracts of several cases of facial hemiatrophy. The first is recorded by Borgherini (*La Psichiatria*, viii, fas. 3 and 4). The patient was a man, aged 63. He had had chronic inflammation of the right lachrymal gland, which was incised. Shortly afterwards he developed localized pain in the right orbit, creeping sensations and a feeling of numbness in the adjacent skin, chronic contraction of the right forehead and face muscles, atrophy of the tissues on the right side of the face, and opacity of the cornea. This condition was on the left limited by the middle line of the face and on the right by the anterior border of the temporal and masseter muscles. The second case is recorded by Muratow (*Vratch*, 1891, No. 25). It is that of a woman who sought advice on account of cramp in the muscles of mastication. This began on the right side and had a clonic character at first, but soon became bilateral and tonic. There was atrophy on the right side of the face, affecting both the lips and the tongue. There were no electrical alterations in the muscles. There were several pigmented spots on the side of the face, and the skin had the appearance of scleroderma, but this condition had appeared before the cramp in the muscles. The third case is by Jankau (*Deut. med. Woch.*, 1891, No. 26). The patient, a girl aged 22, had for two years noticed great pallor with yellow pigmentation and atrophy of the right side of the face, extending over the distribution of all three branches of the trigeminus, and she had lost much hair on the affected side. About the time of the appearance of the hemiatrophy the patient began to suffer from enlargement of the thyroid and ozæna. The next case is recorded by Dixon (*Dublin Journ. of Med. Science*, February, 1891). In a boy, aged 11 years, there followed upon a violent blow over the left hip scleroderma of the left half of the body, the left side of the face, and the left extremities, with atrophy of the affected arm and leg, hemiatrophy of the face, and alopecia of the left half of the body. The last paper is by Girard (*Revue Méd. de la Suisse Romande*, 1891, No. 6). He cut through the sensory portion of the trigeminus in the skull in dogs, and this was followed by hemiatrophy of the face, atrophy of the muscles of mastication, thinning of the skin, atrophy of the bones and of the tongue on the same side. He therefore concludes that the trophic fibres for the face run in the trigeminus and not in the facial nerve.—*Brit. Med. Jour.*

LARYNGEAL PARESIS AFTER INFLUENZA.

Dr. Marcellin Cazaux records a case (*Rev. Gén. de Clin. et de Thér.*, June 10th, 1891) in which paresis of the glottis-openers followed influenza. The patient was a girl, aged 21, who, with the exception of two or three slight and transient attacks of aphonia, had enjoyed good health till December, 1889, when she suffered severely from influenza. In the course of the attack she began to suffer from dyspnœa with inspiratory stridor, and, after her recovery from the influenza, this symptom persisted till July, 1890, when she came under the notice of Dr. Cazaux. The dyspnœa was always well marked, but there were from time to time alarming exacerbations. The voice was clear and expiration was unobstructed. No cause of compression of the trachea, bronchi, or recurrent nerves could be discovered, and the thoracic organs appeared to be sound. On laryngoscopic examination, it was seen that the ligamentous part of the glottis opened incompletely during inspiration. The diagnosis of paresis of the crico-arytænoidei postici muscles was arrived at, and the following treatment ordered: Daily applications of the continuous current to the recurrent nerves, and sulphate of strychnine in 1 milligramme pills—from four to ten of these to be taken daily till intolerance was manifested. In three months the patient was completely cured.—*Brit. Med. Jour.*

A REMARKABLE CASE OF EMPYEMA.

Dr. Felix Szontagh publishes in a Hungarian medical journal a remarkable case of empyema. A little girl of six years old exhibited symptoms of fever; the temperature was 99.5°. The author saw the patient two days after the commencement of the illness, and diagnosed pneumonia of the left lower lobe. Later on symptoms of pleuritic effusion became prominent, although bronchial respiration was audible over the whole half of the thorax. The apex beat was at the right border of the sternum. Nine days later on, an experimental puncture was made in the sixth intercostal space in the middle axillary line. Pus was found, and the next day Dr. Verellélyi made an incision. After a discharge of three ounces of non-fetid pus a drainage-tube was inserted, the thorax washed out with a 30 per cent. tepid solution of boracic acid, and the wound dressed. So far the case presented nothing remarkable, but the author had during the operation been surprised by the relatively small quantity of pus. The state of the patient did not alter, although she was free from fever during the whole day after the operation, and the following evening the temperature had not risen higher than 101.3°. A profuse discharge of pus took place at the next dressing, so that consequently a retention of pus could not be suspected. On the third day the patient got worse, and the previously existing cyanosis increased. During the next three days, however, the patient seemed to improve again, the appetite became better and her general state more satisfactory, but the examination of the chest indicated the presence of some complication. The apex beat was still in the right mamillary line, and it was suspected that, independently of the first effusion, a second had been formed. This suspicion became stronger on observing the remarkable dulness, especially in the upper lobe. A week after the operation, on changing the dressing the secretion was most profuse, and the author concluded that two puriform cavities communicated with each other. The discharge had, however, decreased again the next day. A new experimental puncture was then made in the fourth intercostal space, and although the patient was exceedingly thin the needle had to penetrate to a depth of twenty-two millimetres before any pus was reached. A free opening which was made the next day completely justified the author's expectation, as a pint of pus was discharged. This contained no Koch's bacilli, but diplococci, resembling pneumococci, partly free and partly embedded in leucocytes. The case then progressed most favorably towards recovery. When the patient was shown to the Medical Association, the left lung was not quite fully dilated, as the percussion sound was slightly muffled and the respiration in the lower posterior part of the lung weakened. The deviation is visible at the spine, but hardly present in the thorax, though the circumference of its left half is a centimetre less than that of the right. The case is remarkable for the presence of a multilocular suppurative pleurisy, the correct diagnosis made, and the perfect recovery of the patient. The author presumes that the empyema was formed at the beginning in two places, or that the separation into two cysts took place at a very early stage of the case. If the first operation had been delayed until the formation of pus had reached its maximum, the bilocular nature of the effusion might very easily have been overlooked, and the chances of a recovery considerably lessened. The author repeats his old maxim, "Ubi pus ibi evacua."—*Lancet.*

BACTERIOLOGY OF YELLOW FEVER.

Domingo-Freire has described the amaryl microbe, or cryptococcus xantogenius, which is round and has a diameter of one-thousandth of a millimetre. This micro-organism is only found in the tropics. Quite often the cryptococcus is arranged in little chains; in cultures it gives rise to yellow and black pigments. The former is soluble, and stains the skin of persons with yellow fever; the latter gives color to the vomited matter. When the blood of yellow-fever patients or a culture of the microbes is injected into guinea-pigs, yellow fever is produced; the ptomaines only produce certain symptoms. Transplantation attenuates the cultures, and it is possible to protect the human system from the malady. Inoculation produces a group of phenomena which are similar to those of the invasion of yellow fever; in forty-eight hours the symptoms have disappeared. Sometimes icterus is produced. Domingo-Freire has made a large number of inoculations; the average mortality of inoculated subjects is four-tenths of one per cent.—*L' Union Méd.*, Sept. 5, 1891, p. 347.

SURGERY.

RESULTS OF EXTIRPATION OF THE LIVER.

In a preliminary note Dr. von Meister confirms from his own experimental observations some of the results previously obtained by Ponfick of the remarkable degree of reparative power exhibited by the liver, and applicable doubtless to other glands in greater or less degree. Thus he finds that in the dog and cat, as well as in the rabbit, the removal of more than three-fourths of that organ is not followed by any serious consequences, and that within the space of thirty-six days repair has advanced to such an extent that the weight of the organ is regained. This regeneration is effected partly by hypertrophy of the hepatic cells, but mainly by their hyperplasia; but new lobules are not formed, and biliary ducts as well as blood vessels share in the new formation. Observations were also made upon the effect of extirpation of such large portions of the liver upon the excretion of urea. It was found that the total quantity of nitrogen notably diminishes, but not in proportion to the nitrogen of the urea, so that the proportion of the latter to the whole nitrogenous excretion is decreased. On the other hand, the amount of extractive matters is increased, and their nitrogenous constituents appear in greater proportion than normal to the total nitrogen. The diminution in urea is proportionate to the amount of liver substance removed, total extirpation of the organ leading to a very marked decrease in urea. It was further found that after partial extirpation—within a period of from eleven to fifteen days—the quantity of urea rises until it once more attains the normal degree.—*Lancet.*

EXTIRPATION OF VARICOSITIES FOR ULCER OF THE LEG.

M. Quenu stated recently to the Societe de Chirurgie that he had a report from M. Carne who had operated on a woman of 30 by removing a large varicosity and the internal saphenous vein for ulcers of the leg. Cure occurred in three weeks and complete disappearance of the ulcers shortly afterward. The pathology of these ulcers is claimed by some to be due to a periphlebitis, whereas others claim that paralysis of the vaso-motor nerves is concerned in their production. For this latter reason the removal of the veins is discountenanced by some, except in such cases where extensive ulcers and marked varices exist.

SUTURE IN SIMPLE FRACTURE OF THE CLAVICLE.

Dr. Poirier holds that in certain cases of simple fracture of the clavicle it might be found advisable to expose the injury by incision, and to apply a ligature either of silver wire or silk in order to keep the fragments in good position. This operation, which was first performed by Langenbuch in 1882, has since been much criticised. A recent case is reported in which Dr. Poirier made an incision over a simple comminuted fracture of the left clavicle, removed a detached osseous splinter, and fixed together by silver wire the two main fragments of bone. He describes certain features which would, in his opinion, indicate, in recent fracture of the clavicle, treatment as above. He mentions cases of severe subcutaneous injury of the vessels or nerves of the neck, in which it has been found necessary to make an incision in order to arrest hæmorrhage, or to search for a divided nerve; the broken bone being thus exposed might be sutured without any further risk. This treatment, it is held, is indicated also in cases of comminuted fracture with one or more displaced fragments, which might, in course of time, give rise to some disturbance of the brachial plexus, or result in the formation of masses of callus, in which the subjacent nerves are involved.—*Semaine Médicale.*

THE OPERATION FOR CLEFT PALATE IN TWO SITTINGS.

In a note read at one of the summer meeting of the *Société de médecine de Paris*, published in the *Union médicale* for November 21st, M. Polaillon recommends this procedure as being less fatiguing to both patient and operator. At the first sitting he traces the lateral incisions, frees the mucous membrane, scrapes the bone, and checks any hæmorrhage there may be by compression, sometimes with a hæmostatic forceps. On the next day or the day after he refreshes the flaps, which are now somewhat swollen and tend to approach the median line, and then inserts the sutures, with the great advantage that the hæmorrhage is trifling. He thinks this method insures success even in the most difficult cases.

THE RESULTS OF TREATMENT OF SIMPLE FRACTURE OF THE SHAFT OF THE FEMUR.

At a meeting of the American Surgical Association held in May, a committee consisting of several representative surgeons of the United States was formed with instructions to report on what, in their opinion, might be considered satisfactory results of ordinary treatment of fracture of the shaft of the femur. The report, which is published in the Philadelphia *Medical News* of September 26th, deals with the points of bony union, of the relation of the long axes of the fragments, of correspondence of the anterior surfaces of the fragments, of the length of the injured limb, and of lameness, and concludes with the following summary: A satisfactory result has been obtained in the treatment of fracture of the shaft of the femur when (1) firm bony union exists; (2) the long axis of the lower fragment is either directly continuous with that of the upper fragment, or the axes are on nearly parallel lines, thus preventing angular deformity; (3) the anterior surface of the lower fragment maintains nearly its normal relation to the plane of the upper fragment, thus preventing undue deviation of the foot from its normal position; (4) the length of the limb is either exactly equal to that of its fellow, or the degree of shortening falls within the limits found to exist in 90 per cent. of healthy limbs—namely, from one-eighth of an inch to one inch; (5) lameness, if present, is not due to more than one inch of shortening; (6) the conditions attending the treatment prevent other results than those obtained.—*Brit. Med. Jour.*

THE FORMATION OF A GASTRIC FISTULA IN CANCEROUS STENOSIS OF THE CARDIAC END OF THE STOMACH.

Dr. Lauenstein advises that in cases of marked cancerous stenosis of the cardiac end of the stomach, it is better not to resort to formation of a gastric fistula. He has had two cases of carcinoma of the cardia, in which access to the stomach was prevented by the tumors which were situated under the diaphragm. The neoplasms had invaded the mucous membrane of the stomach, which had to a great extent lost its digestive functions. It may also happen that the stomach is so firmly fixed by adhesion of the tumor at the cardia that the formation of a fistula is attended with great difficulties. For these reasons the author prefers rectal alimentation in this class of cases. A cancer of the cardia should be suspected if the œsophageal bougie encounters resistance at a depth of 38 to 41 centimeters from the teeth. In one of his cases the author noted a loud systolic sound in the epigastrium, synchronously with the pulse, which the autopsy showed was due to pressure of the tumor on the aorta.—*Centralbl. f. Chirurgie.*

THE RESTORATION OF DEFECTS IN TENDONS.

Kümmel (*Weiner medizin. Présse*, No. 43, 1891) has reported the case of a coachman who, while managing a pair of balky horses, perceived a sense of pressure, followed by severe transitory pain, involving the whole of the left arm. Shortly thereafter a swelling appeared in the region of the left wrist-joint, the functional activity of the hand, however, remaining unimpaired. Several hours later severe pain in the left arm appeared. The thumb hung limp, and could be neither adducted nor extended; it felt numb and cold. The injury was considered a luxation, and treated by means of applications of lead-water. At the end of three weeks there remained no doubt that the extensor pollicis longus had been ruptured. Upon opening the sheath of the tendon it was found that the central extremity had retracted to the middle of the forearm. The distal extremity lay rolled up on the metacarpal bone of the thumb. Attempts to approximate the two segments proving unsuccessful, the diastasis of almost four inches was supplied by moderately strong, twisted silk thread. The wound in the skin was closed, and the extremity was dressed in hyperextension. The first change of dressings was made at the end of two weeks, the position of hyperextension being from time to time

gradually relaxed. At the end of six weeks the splint was permanently removed, and movement was carefully instituted. In the course of four weeks more the patient was able to use the thumb with considerable force. The case demonstrates the possibility of replacing defects of tendons by non-vital structure, with restoration of function. It is possible that the silk threads furnish a guide and support for the connective tissue that is to replace the defect.

OBSTETRICS.

HISTOLOGICAL STUDY OF PUERPERAL ENDOMETRITIS.

Bumm (*Archiv für Gynäkologie*, Vol. xl, Section Third, 1891) contributes an article on puerperal endometritis, studied from a histological standpoint. He describes puerperal infection according to the method of invasion; in other words, according to the highways by which the infecting germs find entrance into the organism, whether through the finer lymphatics lying between the fibres of the uterus, or through the larger lymphatics or through the uterine veins when thrombi are present (puerperal pyæmia). This is contrary to the recent classification of Vidal, who describes the various forms of infection according to the influence of each upon the tissue affected—namely, the purulent, the diphtheritic and the septicæmic form.

It has long been known that the entrance of septic material occurs principally through the endometrium. This is shown by the readiness with which the early symptoms of infection are controlled by local treatment, in the form of uterine douches. The foul, infiltrated appearance of lesions of the vulva and vagina during puerperal infection is not due to local irritation at the site of invasion, but to the effects of the general process. The writer wishes, however, to call attention to the different processes affecting the endometrium in the different forms of infection. He describes, first, a putrid endometritis, in which the saprophytic micro-organisms are found, while those characteristic of septic process are absent; second, a septic endometritis, in which streptococci are present in abundance, and which offers for consideration two distinct processes—namely, a localized, septic endometritis, without a general infection, and a local process accompanied by a spread of the septic material through the general organism by means of the lymphatics of the uterus.

An important distinction in all these forms is the occurrence of what the writer designates as the granulation zone. In the first form a zone of infiltration, marked by the accumulation of small, round cells, divides the affected tissue from the deeper lying muscular tissue. The necrotic endometrium is thus cast off, and the uterus is freed from the local process. In the localized septic form the reaction zone also protects the organism from invasion, while in the form accompanied by general infection the micro-organisms find their way into the muscular tissue of the uterus, and hence to the peritoneum by means of extension along the lymphatics without the appearance of any local reaction.—*Univ. Med. Mag.*

AN EFFECTIVE METHOD FOR THE INDUCTION OF ABORTION.

Ræther, at the September meeting of the Hamberg Obstetrical Society (*Centralblatt für Gynäkologie*, No 42, 1891), advocates the following plan of inducing abortion: Under ether, dilate the cervical canal; clear out the uterine cavity with the finger and, if necessary, a placental forceps. Scrape the placental site with a dull curette, and pack the uterine cavity with iodoform gauze, leaving an end projecting from the crevix to secure drainage. Done aseptically, this method is safe, effective and rapid, and does not show the patient and bystanders how they could perform such an operation themselves in another case.—*Univ. Med. Mag.*

ANTISEPSIS: PUERPERAL MORTALITY IN PARIS HOSPITALS.

Our own correspondent in Paris last week gave interesting particulars confirmatory of the immense benefits conferred on parturient women by the application of antisepsis to obstetrics. We commend the account to the careful attention of our readers. He says, out of 1340 women delivered in Prof. Tarnier's wards during the past academical year, only fourteen died, thus giving a very satisfactory mortality of 1 in 95, or 1.04 per cent. Eight years ago the mortality calculated on the same number of cases reached 2.50 per cent.; while, thirty years ago, one parturient out of eleven, or 9 per cent., died. These figures prove conclusively that modern methods of conducting labor are responsible for the saving, in his wards alone, of 100 valuable lives per annum. This is a very gratifying report of progress and advance, and perhaps our correspondent is right in

thinking that the virtue of antisepsis can go no further. Puerperal fever is now unknown in the wards of M. Tarnier, whose memory goes back to a time when he witnessed five deaths in one day from puerperal peritonitis; but there is still room, perhaps, for better results if we may judge from the experience of some of our London lying-in hospitals. In one of these, during the years of 1888 and 1889, there was but one death in 1272 successive deliveries.—*Lancet.*

ETIOLOGY OF HYPEREMESIS GRAVIDARUM.

Keil (*Münch. med. Woch.*, October 13th, 1891) records a case in support of Kaltenbach's view that the vomiting of pregnancy is, in the absence of any pathological cause, not infrequently hysterical in character, and to be treated as such. His patient, aged 26, although a sensitive, irritable woman, had never shown definite symptoms of hysteria. Soon after marriage severe morning sickness set in, without any local causative condition, and unaffected by the usual remedies. Rapid emaciation and debility followed, with fainting attacks, almost every meal being rejected soon after it had been swallowed. On examining his patient with the idea that she might be suffering from hysteria, Keil found conclusive evidence. The ovaries were tender; there was partial anæsthesia of the left arm; pressure over the sensitive second rib caused deglutition movements and coughing, all of which satisfied him that the vomiting was hysterical. The treatment adopted was by suggestion, the patient being told that a newly discovered unfailing remedy (ingluvin) would be given her, and that by washing out the stomach the source of her trouble would be removed, by dieting her on ice and milk, and by isolating her from her relatives. These means proved entirely successful; the vomiting ceased, her general condition improved, and she gained considerably in weight. The symptoms and the results of treatment alike proved the hysterical nature of the vomiting, which had evidently broken out during pregnancy in a woman who was disposed to neuroses.—*Brit. Med. Jour.*

During the progress of the Hyderabad experiment (says the *Hospital Gazette*), several female monkeys were fitted with apparatus to resemble the feminine corset, and chloroform administered. Two died promptly, and the others were saved with difficulty.

GYNÆCOLOGY.

ETHER INJECTION AFTER ABORTION: TEMPORARY PARALYSIS.

T. Féaux, of Gondelsheim (*Centralbl. f. Gynäk.*, November 14, 1891), was called to a patient who had aborted. When he arrived she was greatly exhausted, having lost much blood. The process of clearing the uterus thoroughly of its contents proved difficult, and at the end of the necessary manœuvres serious collapse occurred. Two hypodermic injections of ether were made in the posterior aspect of the upper third of the left forearm. On the second day the patient complained of a sensation of numbness in the left hand. On investigation it was found that the middle, ring, and little fingers were flexed and could not be extended at will. At the end of a month the paralysis remained unchanged; electricity had not yet been tried. The part was now galvanized, and within four weeks recovery followed. Féaux adds that, even at the end of a year, the affected hand remained weak, so that it was easily fatigued. *Brit. Med. Jour.*

THE INFLUENCE OF OBESITY ON THE FEMALE SEXUAL FUNCTIONS.

Dr. Juan Maria Rodriguez writes on the influence, in Mexico, of obesity on menstruation, conception, pregnancy, childbirth, and the puerperium. Fat women are generally irregular in their functions. Menorrhagia is rare; dysmenorrhœa is common. So is amenorrhœa, simple and exfoliative. Amenorrhœa and dysmenorrhœa often alternate. Temporary suspension of the menses is often mistaken for pregnancy, aided by desire and imagination, which latter the author calls "a crazy woman residing in the brains of every one who thinks." Obesity is often a cause of sterility by producing fatty degeneration and atrophy of the ovaries and uterus. Obesity may favor miscarriage, through compression and disturbance of the circulation; it may be a cause of prolonged and difficult childbirth, by impairing the tonicity and contractility of the muscles, and retarding likewise the expulsion of afterbirth, and necessitating bandaging and compression of the stomach after its expulsion. Fat women are considered to be bad wet-nurses.

Obesity is a complaint of rich women. Behier told one of his rich clients, who complained of obesity, to live on three francs, but to earn them by her own work.

In the treatment of obesity, amylaceous food should be abandoned; exercise and steam-baths are useful. Sterility caused by obesity may be relieved by removing the cause.—*Gaceta med. de Mexico*, vol. xxxvi, 1891, p 289.

PÆDIATRICS.

ON VISCERAL HÆMORRHAGES IN STILL-BORN CHILDREN; AN ANALYSIS OF ONE HUNDRED AND THIRTY NECROPSIES.

Spencer (*The Lancet*, June 20, 1891) in a paper giving a detailed account of a consecutive series of one hundred and thirty necropsies, on fresh, mostly still-born, fœtuses, discusses the causation of the hæmorrhage, and reaches the following conclusions:—

1. In children still-born, or dying shortly after birth, congestion or œdema, and hæmorrhages are usually found in various important viscera.

2. These hæmorrhages occur in cases delivered either naturally or by version, or by forceps, through normal or abnormal pelves; in primiparæ and multiparæ; with large and small children; in "easy" and difficult, rapid and prolonged labors.

3. These hæmorrhages are, however, most frequent and severe in children subjected to much pressure by the parturient canal, or instruments, or the hand of the attendant, especially when delivered by the lower extremity.

4. Cerebral hæmorrhage is more frequently found in still-born children delivered by the forceps than in those born by the breech, and in these latter more frequently than in those born naturally by the head.

5. Hæmorrhage into most of the other viscera is more frequently met with in pelvic than in cephalic presentations.

6. These hæmorrhages and the accompanying injuries are in many cases the cause of still-birth, and when not immediately fatal may be followed by the gravest consequences.

7. They are most likely to be avoided by preventing premature rupture of the membranes, by artificial dilatation of the parturient canal (when necessary), by restricting the employment of version and other artificial manipulations to urgent cases, and by preferring cephalic to podalic version in cases suitable for the former.

8. The use of the forceps should be absolutely limited to cases in which there exists some pressing danger to mother or child, and it should never be employed merely to shorten the time of labor.

9. In breech presentations, examinations of the genital organs of the child should be carefully avoided during delivery. As soon as the child's limbs are born they should be wrapped in a thick layer of antiseptic wool. If traction be necessary it should be made over wool wrapped around the child's limbs or pelvis. It should never be made by the hand around the child's waist.

10. In delivering the after-coming head, care should be taken that the sterno-mastoid muscles are not unduly stretched or pressed upon. When the after-coming head is in the pelvis, where there is even slight difficulty, resort should be had to the forceps.

COMMON THYME IN WHOOPING-COUGH.

Common thyme, which was recommended in whooping-cough three or four years ago by Dr. S. B. Johnson, is regarded by Dr. Neovius, who writes a paper on the subject in a Finnish medical journal, as almost worthy of the title of a specific. During an epidemic of whooping-cough he had ample opportunities of observing its effects, and he came to the conclusion that if it is given early and constantly it invariably cuts short the disease in a fortnight, the symptoms generally vanishing in two or three days. They are liable to return if the thyme is not taken regularly for at least two or three weeks. He gives from one ounce and a half to six ounces per diem, combined with a little marshmallow syrup. It may produce a slight diarrhœa. It is important that the drug should be used quite fresh.—*Amer. Jour. Med. Sci.*

ETHERIZATION IN LARYNGEAL CROUP.

Dr. Betz reports the case of a child, aged eighteen months, that presented the typical symptoms of laryngeal croup. The case appeared so hopeless that tracheotomy was, although proposed, rejected. Dr. Betz then proposed "etherization." Three drops of a mixture of ether sulph. 3 parts, acetic ether 1 part, menthol 0.1 part, were ordered to be inhaled every quarter of an hour, just as chloroform is inhaled. It was hoped that the cold from the evaporating mixture would contract the surface blood-vessels of the larynx, and thus reduce the œdema present. The child was seen again in two hours, and the condition had somewhat improved. The etherization to be continued, three to four drops every half-hour. After six hours the

condition was unmistakably better, so much so, in fact, that the etherization could be dispensed with. A piece of intestine filled with ice was placed around the child's neck. After this progress was so rapid that in twenty-four hours the child was out of danger. —*Memorabilien.*

HYGIENE.

ON TAKING FLUID WITH MEALS.

A great deal of misapprehension is often found to exist in the popular mind in regard to matters of eating and drinking; the cause of this, to some extent, is to be traced to old-time sayings which have come down to us in the form of a concentrated infusion of somebody's opinion upon a subject of which he or she was woefully ignorant. One of these misapprehensions to which we may refer is as to the injuriousness of taking fluid with meals. One frequently hears it laid down as a maxim that "it is bad to drink with your meals, it dilutes the gastric juice." By way of explanation we may remark that "it implies that the fluid taken is harmful." Whence this sagacious postulate originally came we cannot tell; it has quite the ring about it of an inconsequent deduction formed by a person whose presumption of knowledge was only exceeded by a lamentable ignorance of the subject. Medical men often find much difficulty in dealing with these museum specimens of antiquated science, for even educated persons are disposed to cling to the absurdities of their youth. Upon this matter Mr. Hutchinson remarks in the last number of his "Archives:" "I observe with pleasure that the verdict of general experience and common sense has been confirmed by scientific experiment in the matter of taking fluid with meals." Dr. Tev. O. Stratievsky, of St. Petersburg, after elaborate trials, has found that fluids materially assist the assimilation of proteids, and announces the following conclusion, which it is to be hoped no future experiments will controvert: "On the whole, the widely-spread custom of taking fluids during or just before one's meals, proves to be rational and fully justified on strict scientific grounds. To take fluids with the meals is almost as important an adjunct to digestion as is the mastication of solid food preparatory to swallowing it." It is obvious, however, that there is a limit to the amount of fluid one can swallow with impunity—not to speak of comfort—just as much with meals as at other times. It would be dangerous to create a general impression that fluid is good with food irrespective of quantity. It is, moreover, a well-ascertained clinical fact that an excess of cumprandial fluid does retard digestion in certain people, and gives rise to discomfort in most. A little attention to one's sensation in such matters will far better fix the desirable limit than all the "data" in the world.—*Medical Press and Circular.*

PNEUMATIC SOLES.

A pneumatic inner sole or sock for boots and shoes has been brought out to confer great benefits upon people who have tender feet, etc. It is made of hollow India-rubber, inflated with air or gas under pressure, the external protective covering being canvas, linen, skin, or other suitable material, to adapt it to withstand the internal pressure of the compressed air or gas.—*Invention, London.*

DOES ETHER ASSIST DIGESTION?

The effect of ether on digestive processes in healthy subjects has been recently investigated by Dr. Gurieff, who gave thirty drops of sulphuric ether to six healthy persons during dinner, which consisted of about half a pint of soup, four ounces of meat, and six ounces of bread. It was found that the ether had the effect of stimulating the action of the gastric glands, increasing the free hydrochloric acid in the gastric juice, and causing the peristaltic movements of the stomach, together with its power of absorption, to increase thus; on the whole exercising a favorable effect upon the gastric digestion. The same result was obtained when the ether was administered by means of hypodermic injections. It would appear, therefore, that the effects must be ascribed to a general rather than to any merely local action on the mucous membrane of the stomach. Dr. Gurieff is disposed to think that there is a stimulation of the cephalic centres. This view is partly based on the observations of other Russian observers—Bekhtereff and Miloslevski and Pavloff and Shumova-Simanovskaya—on the dependence of the gastric functions upon the central nervous system.—*Lancet.*

IODIDE OF POTASH IN URTICARIA.

Dr. Stern (*Norsk Mag. for Lægevidenskaben,* No. 11, 1891) has used small doses of the iodide of potash in five cases of urticaria with successful results.

MEDICAL CHEMISTRY.

PRESENCE OF FATTY ACIDS IN SO-CALLED DEFATTED COTTON.

The *Pharmaceutische Centralhalle* states that M. Leick, having treated a number of specimens of cotton wadding, sold as entirely free from grease, to exhaustion with ether and subsequent distillation, the author obtained in every case a solid etheric extract varying from ½ of 1 per cent. to 1.15 per cent. of the weight of the cotton so treated. This extract reddened litmus paper, and proved to be composed almost entirely of fatty acids, with a minute proportion of resinous matters. The author, continuing his investigations, found that these acids were purposely added by the manufacturers in order to give the wadding a whiter appearance and that crepitant feeling which is peculiar to it. The author concludes that inasmuch as the presence of acids may be an objection under certain circumstances, he would recommend the testing of all "defatted" cotton wadding in the following manner: Weigh out 20 gm. of the wadding, exhaust by ether, and evaporate the latter. After desiccation, the residue should be no more than 3 cg.

IDENTITY REACTION OF PHENACETIN

W. Autenrieth and O. Hinsberg have recently published a paper on phenacetin and certain of its derivatives in the Archiv d. Pharmacie, volume ccxxix., page 456, in which they first communicate a new identity reaction of the substance, and afterwards give the results of their investigations into the nature of the product of this reaction, and into its constitution.

Identity Reaction for Phenacetin.—Upon 1 part of finely powdered phenacetin pour 2 parts of nitric acid containing 10 to 12 per cent of HNO_3 (specific gravity about 1.075), and heat for a short time to boiling. The liquid will assume a yellow to orange color, and the phenacetin, which had at first remained colorless, will at the same time (so far as it is not dissolved) be converted into a nitro compound of an intensely yellow color. When the liquid cools, a further crop of needles of the yellow (or brownish-red) compound crystallizes out.

Antifebrin and antipyrine remain unaffected when treated in this manner.

If concentrated nitric acid is used, however, antifebrin is colored yellowish-red, and antipyrine yields a red solution.

The meeting point of the characteristic yellow derivative of phenacetin, which was subsequently recognized as *mononitrophenacetin*, or $C_6H_3.OC_2H_5(4).NO_2(3).NHCOCH_3$ (1), is at about 103° C.

THE CONSTITUTION OF THE SWEAT.

From a study of the constitution of the secretion of the sudoriferous glands, Gaube, (*Comtes Rend. des Séances de la Soc. de Biol.*, November 6, 1891) has found that the sweat is of acid reaction in man, but alkaline in the horse, the cow, the dog, the cat, and the pig. Both in animals and in man the secretion contains albumen. The total amount of nitrogen in the sweat is greater than that represented by the contained urea; the excess is largely due to the presence of albumen and albuminoids. In man and in animals the sweat contains diastasic ferments, which are called hidrozymases. In man there are three—an amylase, a pepsin, and an emulsin; in the horse there are two: an amylase and an emulsin. The sweat of man contains little amylase, less pepsin, and still less of emulsin, that of the horse and of several other animals contains less hidrozymases than does the sweat of man.

THE ACTION OF PARASITICAL PLANTS ON THEIR HOSTS.

At a recent meeting of the Academie des Sciences, M. Chatin, speaking on this subject, said that all parasitical plants seriously modify the sap of their hosts, totally eliminating some elements, and on the other hand producing other new ones. He cited as examples the loranthus grown on *strychnos nux vomica*, in which no strychnine is found; botanophora grown on cinchona, in which no quinine is found; and, in the oak-mistletoe, green instead of blue tannin is found. On the other hand, substances are found in parasites which do not exist in the trees on which they are found. Thus, mistletoe contains lime, and the dodder produces yellow and red coloring matters. In the broom-rape of hemp and milfoil a blue color is found; in that of the horseshoe vetch, a rich sulphur tint; and in the broom-rape of thyme, an amethyst shade. The mistletoe and most other parasites contain fecula, which penetrates to the fibre of the wood. In short, all these matters are formed by the parasitical plants themselves.

THE presence of the circus poster excites the small boy to deeds of daring and lands him in the hospital cot.

NEWS AND MISCELLANY.

THE HORRIBLE GRIP.

[With apologies to the author of "Beautiful Snow."]

Oh the grip, the horrible grip!
That comes along with an impudent nip,
In head or stomach, with sneaking stealth,
And lays a chap, though in excellent health,
Quite surreptitiously out on his back,
With all of his energy gone, alack!—
Sneezing,
Coughing,
Groaning—a sip
Of the terrible malady known as the grip.

Oh the grip, the horrible grip!
Which doubles one up like a chicken with pip,
And makes him feel as though he should freeze,
Though hugging the stove with close-crossed knees,
And taking quinine grain after grain,
While fairly yelling with internal pain—
Shaking,
Shivering,
Shuddering, too,
Since the grip has a grip till he's fairly blue.

Once I was well as the healthiest man,
With every disease that was known under ban—
Rollicking, jolly and happy, indeed,
As a man with never an earthly need;
But now I shiver whenever I hark,
And growl in a sort of Peruvian bark—
Muttering,
Grumbling,
Swallowing a nip,
So bitter, to drive off the horrible grip.

Oh the grip, the horrible grip!
Wherever it come from, in schooner or ship,
As an immigrant, 'tis the most ruthless of bores,
And ne'er should have landed upon our fair shores.
The ghost of diseases, it stalks on its way,
With a most unrelenting, terrible sway,
Mocking,
Jibing,
Lickety-zip—
Yes, that's the fatality known as the grip.
—*Philadelphia Press.*

WANTED, A CURE.

The influenza is once more in the air, wafted hither and thither throughout the habitable globe, a formidable, disabling and fatal pandemic. Once more we are urgently asked on all sides, "Have we a specific? Can we offer a cure?" It is the old delusion and the everlasting and unreasoning, but excusable, impatience for the miraculous and the impossible. "Disease comes by Providence and goes by medicine;" that is a durable and popular formula. Of specifics for sale there are of course a legion. To sell them is the business of the quacks: the Matteis, the Holloways, the Morrisons abound in specifics. There are a dozen available for cholera, for typhoid, for small-pox, for hydrophobia, for cancer—all equally plausible and equally useless except for commerce—and why not for influenza? But is there a specific for any disease? It is more than doubtful. The more we know of the nature and cause of disease, of its origin and life-history, the less we are inclined even to expect the discovery of specifics. Disease we know not as an entity, an enemy to be struck down with a club, or to be expelled by a drug, but as a process, the change of tissues and of fluids, the growth of a microbe, the proliferation of a cell, the secretion of a virus. We can modify the processes, we can lessen their virulent products, we can fortify against their worst effects; we can aid the evolution and perhaps guide it to health; sometimes we can arrest it; and often we can anticipate it. Thus we know how to ward off many diseases: Cholera, typhoid, small-pox, hydrophobia, they are enemies whom we can meet at the gate and forbid their approach. Deaths from either of these preventable diseases are for the most part violent deaths, inflicted by the ignorance of the people, the neglect of the sanitary authorities. *Populus vult mori.* In their search for specifics they parley with the enemy and they lose their lives. Of influenza we know less than of most other infections; it is aërial, communicable from person to person, and along the lines of travel. For it, as for scarlet fever, we have only isolation as a preventive and palliatives as a treatment. Perhaps one day we shall know more; but there does not seem any likelihood of the discovery of a specific, and, judging from numerous analogies, it is far from certain that there is in this any ground for reproach. At any rate, it comes badly from a public and from a generation which is content to leave Great Britain without even one Institute of Preventive Medicine, and which is left to an appeal for funds from a Lister and a Roscoe to found such an institute—in which lies a chief hope for further life saving and the advance of preventive and curative knowledge—while millions are lavished on weapons of destruction, or the more obvious means of charitable relief to physical suffering; and finally on the purchase of fradulent "specifics."—*Brit. Med. Jour.*

"ARE you the judge of reprobates?" said Mrs. Partington as she walked into an office of a judge of probate. "I am the judge of probate," was the reply. "Well, that's it I expect," said the old lady. "You see my father died detested and he left several little infidels, and I want to be their executioner."

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. JOHN V. SHOEMAKER, of Philadelphia, Pa. Professor of Materia Medica in the Medico-Chirurgical College of Philadelphia. "Peroxide of Hydrogen." *Materia Medica and Therapeutics, with especial reference to the Clinical Application of Drugs.* Vol. II., page 681.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

SUPRA-PUBIC CYSTOTOMY. — UNUNITED FRACTURES—AMPUTATION OF ANTERIOR PORTION OF THE FOOT.

BY JOHN H. PACKARD, M. D.

SURGEON TO PENNSYLVANIA HOSPITAL, PHILADELPHIA.

The case which I shall present first this morning is one of considerable interest as it illustrates an operation which, practised long ago and then abandoned on account of its supposed dangers, has recently come into vogue again. This old gentleman was brought into the hospital on August 18th, suffering from retention of urine due to a very much enlarged and lobulated prostate; the bladder was distended until it reached far above the umbilicus. We spent very little time in trying to pass an instrument to draw off the water. He was in a wretched condition, and I decided at once resort to supra-pubic cystotomy. This is the easiest of all methods of reaching the bladder, and in cases of enlarged prostate it affords special advantages of which the perineal section is destitute. In this case, the urine flowed away very freely, and the man was immediately and entirely relieved. In order to keep up this condition of relief, a rubber tube was passed into the bladder and his water has been drawn off continuously by that means. Now it will not do for the man always to go with a rubber tube in his bladder, because, as you can readily see, it will be difficult to manage and hard to keep clean. Therefore to-day I am going to try to introduce a curved glass drainage tube; fitted exactly to the bladder in its relation to the wound and to surrounding structures. Such a tube will drain without any trouble, and will not soil his clothes.

The incision which I made in this case was about four inches long, directly over the bladder, the condition of which gave us a perfect indication of the point at which it was to be entered. I cut through the skin and superficial fascia, the deeper layer of the fascia, the rectus and pyramidales, and then came to a layer of fat which was triangular on section; and just below that, the bladder was distinguishable by its grayish-blue color, and by its longitudinal fibres of muscle which are in its wall. At this point I took hold of the bladder with a tenaculum and opened it, so that I could pass the rubber tube into the bladder, as you see. Now I am going to pass the glass tube in and see if it fits perfectly; and if not, I shall have another made. Then I will fasten a rubber tube over the double shoulder which is on the end of the tube, and which it would be well to have on all drainage tubes used after abdominal operations.

On passing this tube I find it is a little too long and would press on the mucous membrane of the floor of bladder, and there is a tendency to push the tube out, due to contraction of the muscular pelvic floor. Pain in the bladder causes this spasmodic action of the levator ani. I will replace the rubber tube for the present and will have another glass tube made, about one inch shorter, and then I think it will fit exactly into the bladder. On this will be put a rubber tube and this will be closed with a clip. With this arrangement, the man will be enabled to go about, and when he feels that the bladder needs to be emptied, he will merely have to release the clip.

This operation was done over three hundred years ago—many times in the last century, and in the early part of this one. But care was not properly taken to avoid injuring the peritoneum or to drain the bladder. So the operation was often complicated by infiltration of urine or by traumatic peritonitis. A very distinguished London surgeon of the last century used to inject water to distend the bladder previous to this operation, sometimes to the point of rupture; and several accidents of that kind having happened, surgeons gave up the supra-pubic for the perineal operation. Now the fact is, that this

operation is very much easier than the perineal operation. We cannot miss entering the bladder, and it is only in exceptional cases that the peritoneum extends very low down towards the symphysis pubes. For myself, I would much prefer this procedure, when the bladder is distended, as in cases of impermeable stricture, in the hands of an inexperienced surgeon, to the perineal section. The operation has gained great favor in the last four or five years, although its revival was at first regarded with a great deal of doubt. My first experience with it was in 1883, in the case of a man who had in the bladder a large shawl-pin, which could be felt above the pubes. I suggested to the physician that the operation above the pubes would be the best. It was done with perfect ease. After that I had a number of cases in which I entered the bladder in this way, and it seemed to me advisable to call attention to this operation again. Somewhat to my surprise, I found that several surgeons had already had a somewhat similar experience; and it seems likely that this method of entering the bladder may to a great extent supersede that by way of the perineum.

UNUNITED FRACTURE.

This young man has had a fracture of the humerus. The bone failed to unite, and there was considerable loss of substance, and you will see that the fractured arm is much shorter than the other. He came in here after several attempts to produce union, and I determined at first to cut off the ends of the bone and wire them together. When I came to lay them bare, however, the bone was so soft (this is often found to be the case in ununited fracture where there is loss of substance) that it would not hold the pegs or ligatures. I therefore simply drilled the bones and had the arm dressed, which I think will give a satisfactory result. I am told the arm is much firmer, and I find there is a considerable degree of consolidation about the fracture.

I will just call your attention to the line of invasion, which was at the back of the arm, because we could there lay bare both fragments without any very extensive incision, and we avoided all risks of injuring important nerves or blood vessels.

The methods of dealing with cases of ununited fracture are very varied, as you probably know, and the results obtained, unfortunately, are sometimes far from what we could wish. In this case, the youth of the patient and his vigorous health and the soundness of his tissues is favorable generally. I hope he will have a good and useful arm, by which he will be able to earn his living.

The loss of substance of the bones of the arm is a curious clinical fact that has never been explained, so far as I know. There are cases where the entire bone has been absorbed, from the shoulder to the elbow. I have seen another case in which six inches of the bone were lost. However, in that case, even had we succeeded in uniting the ends, it would have been useless, as there was anchylosis of the elbow. And that is another point in all ununited fractures, which in this case we were not able to attend to. Where you have charge of such a case from the first it is important to keep the elbow joint as free as possible, by constant passive motion, to prevent stiffening of the joint.

AMPUTATION OF ANTERIOR PORTION OF FOOT.

The next case is a boy, the anterior portion of whose foot I amputated last Saturday afternoon. It has not been touched since then, and we will see what its condition now is. This boy, who was in good health, had the front part of his foot run over and crushed by a railroad car; it was necessary to take off a larger portion of the foot than I would like to have done. In this case, as you will readily understand, the foot being a lever upon which the patient walks, the risk was that contraction of the tendo Achillis would draw up the short stump, and that when the boy walked, instead of treading on the heel, his weight would come on the stump, which would be tilted down. In order to prevent that, I divided the tendo Achillis and brought the heel down, so that the boy will walk fairly upon what is left of the sole of his foot. That is a very important point in all foot amputations.

I call your attention to this case because, within a very short time, a distinguished surgeon has made a statement which has been backed by others, that where the front part of the foot is damaged, the amputation should be made about five inches below the knee. I could not make such an amputation when I could give this boy a good heel to walk upon.

In this case we meet with what is almost always met with in amputations of the foot, and that is a great deal of hæmorrhage. I presume the time occupied in stopping the hæmorrhage was at least four times as long as that of operation or even of etherization.

On my taking off this dressing you see where the heel is now. It is not turned up at all, as it would have been if the tendo Achillis had not been divided. The operation having been done under strict antiseptic

precautions, the stump is in a perfectly healthy condition. In former times, after amputation of this kind, the wound was always dressed the next day; the day following we generally found some suppuration, and the third day there was generally free suppuration, which we thought a most excellent thing. The stump had to be squeezed, and required dressing every day, causing a great deal of pain for the patient and a great deal of trouble for the surgeon, which is now avoided.

In this case I left only the astragalus and os calcis. That is not the best operation when you can help it; it is better to leave more of the foot, for then the patient has more leverage for walking, but I think you will see that this is very likely to make a good stump. By having a stiff boot, with a sole that will give some spring, the boy will have a foot that will give him an almost natural gait.

What I want to lay special stress on in this case is that the natural heel is better than any artificial leg that can be made. Moreover, in spite of antiseptic precautions, the risk still remains that amputations are more dangerous the nearer they approach the body.

In this stump we used a cat-gut drain and there is no necessity for disturbing it, as the portion within the stump will be absorbed and give no trouble. The stump now needs only a re-application of the dressing. This will not be removed for ten days, unless there is some indication for disturbing it. Probably that will be the last dressing required. The stump has, in this case, been enveloped in sublimate gauze, and you will see that there is no irritation whatever of the skin. You will find that the sublimate gauze sometimes causes an irritation of the skin and occasionally a copious eczema. Such cases are, however, so rare that we generally use the sublimate gauze until we find that it produces irritation.

RANULA.

Briz, of the General Hospital, Madrid, mentions a case of one of these tumors, as large as a hen's egg, which he cured in a very simple way. The contents of the tumor were too thick to be aspirated with a hypodermic syringe, and fifteen minims of the following solution were injected twice, at an interval of three days, and effected a permanent cure:

℞ Potasii iodidi.....gr. vi.
Tinct. iodini,
Aquæ destil.....āā f ʒ i.

A DAY'S EXPERIENCE IN ELECTRO-GYNÆCOLOGY.*

By G. BETTON MASSEY, M. D.,
PHILADELPHIA.

Ladies and Gentlemen:—Before proceeding to the special subjects of this evening's lecture, I desire to say a few words on the attitude that should be maintained by the rational physician in studying the diseases of women. It is probable that no other body of scientific workers has displayed as much personal bias in approaching practical questions as has the medical profession. This is doubtless because its work consists in an analysis of the most complex question of all: man—the acme of creation, and hence the most difficult question to understand in all nature. Lacking complete knowledge of its work, its individual members become unduly impressed with those things they do know, and are ever ready to draw general conclusions from imperfect premises. And if man, as a whole, is so difficult of complete conception in his weaknesses and diseases, how much more so is woman, that gentler and more delicate half of man, with the added refinements of structure and function that characterize her sex? It could only have been this bias in the minds of investigators that could lead them to regard the diseases of women as merely mechanical and surgical. So dominant have become the few things that surgeons do know that all else is forgotten, and we are gravely assured on all hands that gynæcology is but a branch of general surgery. This designation of a part as the whole would concern us but little if it did not constitute the working creed of the most active practitioners of the day, who are, in the midst of much good work, rearing another of those tidal waves of excess that threaten in the inevitable recoil to sweep away their own well-founded work. What has womankind done that renders her pelvic ailments so different from the functional and organic derangements of other parts of the body?

True gynæcology is a broad consideration of the ailments peculiar to women, and thus deals not only with morbid growths and physical deficiencies, but also with an association of functions of so delicate a nature as to be comparable only with those within the cranium. By reason of the abundant sup-

* A lecture delivered at the Philadelphia Polyclinic and College for Graduates in Medicine.

ply of spinal and sympathetic nerves within the pelvis, and the overshadowing importance of nervous phenomena in its three great functions, menstruation, procreation, and gestation, gynæcology should rather be considered a department of neurology than of surgery. With this thought in view how unsatisfactory are our present text-books; and could not something be gained by re-examining our present views of the importance of mechanical deviations in derangements of these functions? Much is said of disorders of menstruation and gestation, it is true, but how little of disorders of the procreative function, imperfections in which, I believe, are at the bottom of a large proportion of the most annoying troubles for which we are consulted. We hear much of lack if virility—why not also of a lack of femininity?

To regulate, conserve and restore function should be our aim in gynæcology, rather than blind amputation of parts we think defective, and hence the physician with his remedial measures has the first right to the field. Neglect of this common-sense rule is daily adding to the host of unnecessary mutilations with which women have been afflicted of late, and has filled many an untimely grave. The careless way in which grave operations are suggested and performed was strikingly illustrated the other day in my service at the Dispensary for Women, where a patient applied for treatment for a pain in her side and slight menstrual irregularity. Examination revealed no apparent deviation from physical normality. She had been sick but six weeks, yet had been advised at another dispensary to have the appendages removed at once. Such an occurrence gives us an inkling of how that other dispensary furnishes a well-known operator with an unusual abundance of material.

But dispensary work gives us an imperfect view of the daily problems of gynæcology. It is the private patient that taxes our skill to the utmost, as it is well known that certain faults in the higher civilization of the day tell especially against the normal performance of function; hence a full illustration of the particular subject of this lecture—the value of electrical applications in regulating, conserving and restoring pelvic organs and functions—requires that both classes of work be represented. I shall therefore take you in fancy with me into office practice, as well as to clinics to illustrate the experiences of a day in electro-gynæcology.

MENORRHSPASM.

I wish you first to consider a case seen to-day at the Dispensary for Women. Imagine a well-proportioned, otherwise healthy married woman of 28, who complains only of a menstrual pain and intermenstrual tenderness. Since puberty she has suffered from an aggravated example of that periodical pain that is the bane of so many young girls and older women—a condition to which I gave the name of menorrhspasm, with its attendant menorrhalgia, some two years ago. Her former physician preferred to call it by the older name of dysmenorrhea, and the tenderness that is now found to the left of the apparently normal uterus is possibly due to the mechanical view of her condition implied in the use of such a term, for she has been dilated twice. Thus a purely surgical view of a neurotic condition induced the use of a method that she thinks left her worse than before.

Recognizing that the primary disease was but a periodical neuro-muscular spasm, to which had been added a moderate degree of chronic inflammation of the left appendages. she was treated by simple vaginal applications of the galvanic current, 40 ma. positive being applied on a cotton-carbon electrode in the left fornix twice a week. She has now passed three periods without pain, and tells us to-day that she was more comfortable at the last one than at any time before in her life. How did these applications accomplish such results? Doubtless by allaying neuro-muscular irritability; by stimulating metabolic activity in the tissues, enabling them to throw off morbid products and conditions; and by combating congestion by virtue of stimulation of vaso-motor nerves.

RELAXATION.

An interesting case seen to-day in office practice bears out the remarks made a minute ago on the importance of a perfect accomplishment of one of the more delicate functions of the pelvic organs. The lady, a multipara, applied to me some time ago for the relief of a backache, a bearing-down sensation, pains in both sciatic and crural regions, and moderate leucorrhœa. A local examination showed the vagina relaxed and overly congested and sagging. There was also a partial laceration of the perineum, which dated from an early confinement. By close questioning it was brought out that the marital duties were decidedly deficient in normal completeness, though by no means painful. Here was a condition not unlike those found in other organs when suffering from neuro-muscular atony, as, for instance, the stomach in nervous dyspepsia. As in such a stomach true hunger is as lacking as is the ability to

comfortably digest food, so here an attempt at functionation without that most potent sauce, hunger, results in an ever increasing enfeeblement and consequential engorgements and irritations. The fault was clearly not in the relaxed mucous membrane, but in the nerves and muscles behind it, and the result proved the surmise to be correct, for a practical cure was obtained some time ago by alternative applications of the galvanic current (vagino-abdominal) supplemented by two slight intra-uterine applications of the same kind. The latter were given by means of the inoffensive elastic spiral electrode, and were 20 milliamperes strong, and a week apart, giving quick relief from the annoying sensations in the back and limbs, which had no doubt been due to the uterine congestion.

Such quick results could not have been obtained in a more chronic case, particularly if the perineum had been badly torn or the muscular substance of the vagina atrophied; but no clinical fact is more patent to me than that the constrictors of the vagina may be made to contract by swelling applications of the galvanic current when not completely torn from their attachments, for I have repeatedly verified it. Faradic applications are also of service, but not nearly so valuable as the galvanic.

I have called this condition *relaxation* for want of a better term, but it is easily seen that this word refers only to a portion of the trouble. There is need for a scientific term for the condition as a whole. The antithesis of dyspepsia, it is by far more common and more productive of morbid consequences.

FIBROID TUMORS.

Within the past few days I have had the pleasure of seeing two former office patients who were under treatment for fibroid tumors of the uterus some time ago, and who kindly came in to report. The results in both have been excellent, and as they have not been reported before I wish to speak particularly of each. The first case was sent to me by a prominent gynæcologist and obstetrician of this city in May, 1890. The patient was 46 years old, unmarried, and had been suffering from hæmorrhages and pain for several years. The growth was larger than a child's head, occupying much of the pelvis and extending up into the abdomen to a point three inches below the umbilicus. Intra-uterine applications of from 30 to 100 ma. were begun and continued for a number of months, the applications being at times negative and at others positive. Prompt relief of pain and hemorrhage ensued, and the patient was shortly able to resume the active life that had long since been impossible; but I was discouraged by a lack of real decrease in size. To accomplish this additional result, if possible, I changed the treatment to intra-uterine alternative applications of 100 ma., that is: the current strength mentioned was turned on gradually with one pole, held a half minute, gradually turned off, and the same procedure repeated with the commutator reversed, applying each polarity about six times at each sitting, the sittings never being closer than a week. By this method chemical electrolysis and its attendant local action was reduced to a minimum, while a maximum galvanic constringent action was obtained, with its attendant effect on nutrition. The good effect of this change was soon manifest, the upper extremity of the tumor receding to four inches below the umbilicus in three weeks, and five inches in eight weeks. The treatment was discontinued by me shortly afterwards, and the patient was asked to return at intervals for examination, which, however, she was unable to do until nearly six months had elapsed. At that time (Sept., 1891) I was astonished to find that the tumor had continued to decrease in size without treatment, and was entirely within the pelvis. When seen to-day there was practically no tumor, the enlarged uterus being guyed to the pelvis in various directions by bands of adhesion that had formerly embraced the tumor itself. The symptomatic cure was equally perfect. The tumor in this case was of the smooth, hard variety.

In the other case the tumor was three-lobed, much larger, and filled the lower portion of the abdominal cavity up to a level with the umbilicus. In constitution it was doubtless more myomatous than fibromatous, as the characteristic menorrhspasm was prominent, she being compelled to remain in bed under the influence of morphia at each period. Under simple intra-uterine treatments of the usual kind, interspersed with vaginal applications, this enormous growth has become gradually absorbed, leaving a uterus that differs from others only by being still nodular, and so mobile as to become easily displaced.

UNIVERSITY ALUMNI DINNER.

The Alumni of all departments of the University of Pennsylvania propose to give a dinner on Saturday, February 27, 1892, at Musical Fund Hall. Eminent speakers among the Alumni are expected to be present. Any graduate of the University desiring to attend may send his check for the amount of subscription, ten dollars, prior to February 17, to John Douglass Brown, Jr., treasurer, 519 Drexel Building.

COMMUNICATIONS.

A FEW OBSERVATIONS ON DISEASES WHICH IMPLICATE THE HIP, KNEE AND ANKLE JOINTS DURING CHILDHOOD.*

By THOMAS H. MANLEY, M. D.
VISITING SURGEON TO THE HARLEM HOSPITAL, NEW YORK CITY.

KNEE-JOINT DISEASES.

The knee-joint being wholly devoid of any muscular envelope laterally or anteriorly, morbid changes affecting its synovial sheath, cartilage, ligaments or bone are more easily recognizable than in an articulation more deeply lodged; and hence, a morbid action in this situation will not, as often here, escape detection in its early stages as in the hip joint. The epiphyseal cancellous heads of bones which form this articulation are very large and have vast articulating surfaces. The ligaments at the knee are more numerous and powerful than in any other articulation in the body. Its synovial capsule, practically divided into four pouches by the patella, is of considerable capacity, of great elasticity, and capable of immense distension. The condyles rest on and play over an extensive area of articulating surface. That formed by the tibial head is very resilient and elastic, thereby effectually guarding against sudden or violent concussive force. The fibro-serous investment of the knee-joint is a very thick, elastic membrane, which is highly vascular. The absorbent power of the synovial capsule is very great; hence, sanguineous, serous or purulent accumulations within it are often quickly disposed of.

Rheumatic and neuralgic affections are very common in the fibrous structure of the knee, the former in the acute and subacute varieties attacking one or both joints. Every one is acquainted with those vague, shooting pains through this joint in childhood during the stages of active growth. Congenital syphilis plays an important rôle in many affections of the knee in which the cellular elements of the medulla, bone and perichondrium are the seat of inflammatory changes.

As the knee-joint is powerfully acted on by muscles of great volume and strength, it follows that functional or organic changes, either within, or exterior to their sheaths, will more or less impede knee action. Their tendons, behind and anteriorly, contribute largely towards maintaining firmness in the joint; hence, are practically accessories to the ligaments.

The most common morbid processes in the knee-joint in childhood are of a rheumatic or tubercular origin. As the question of diagnosis will not be considered here, signs, symptoms, or clinical history will be referred to only when necessary.

Rheumatic inflammation is comparatively of infrequent occurrence in early childhood, and, when present, is not accompanied by a peculiar and characteristic cachexia as is strumous disease. Unlike tubercular invasion, the onset is sudden and is usually attended with a marked hyperexia. We are concerned here only with the non-arthritic, intermittent phase of it. When the fibrous elements of the muscle sheaths, the intermuscular septa and the thecæ of the tendons participate with severe, acute rheumatic arthritic inflammation, it may end in the complete destruction of function in a joint. When the knee or ankle is the seat of rheumatic inflammation, it is much easier of recognition than when the femoral articulation above, is thus involved. In rheumatic arthritis at the knee, synovial effusion is commonly large and promptly appears with the advent of the disease; to the hand, in the early stages of rheumatic inflammation, the integuments will feel dry and hot. It is seldom if ever, we encounter in the unmixed disease that enormous subcutaneous infiltration which gives to the skin the thinned, atrophied and smooth, blanched appearance so peculiar to tubercular arthritis or osteitis. Œdema of the ankle and foot are not commonly seen here; and, although there may be well pronounced joint implication, there is not that tendency to extreme flexion of the leg or the thigh which is seen in tubercular osteitis, arthritis or synovitis. When in doubt as to the presence of a rheumatic element in a given case, one would suppose that the flitting character of the malady and the implication of other joints would decide the question of diagnosis, but, sometimes rheumatism may spend its violence in one articulation. When the synovial effusion is not very great and is wholly serous, with its absorption and the subsidence of inflammation in the peri-arthritic structures, pain and soreness will disappear, and the use of the limb be quickly restored. But, sometimes, there is an abundant effusion of lymph, which is not only freely formed on the joint surface but is likewise elaborated along the muscle and tendon sheaths, which if not absorbed,

* Continued from the last issue of the Reporter.

may undergo organization. Within the joint this material firmly binds the articulating surfaces together, and in time taking on osseous changes will cause true bony anchylosis. Even when the joint may be quite free, yet a plastic effusion into the muscle sheaths and intermuscular spaces, undergoing fibrous changes, will, in varying degrees according to its site and in proportion to its quality and extent interfere with, or wholly destroy, knee-action.

This is of paramount importance to remember, for it reiterates the fact (though it may seem rather a paradox) that a joint may be immovably anchylosed and yet its anatomical structures remain perfectly healthy. The latter is designated muscular anchylosis, but it may be tendinous. When anchylosis or a mechanically fixed position of the limb is maintained in a youth for a considerable period of time, we will invariably have muscular, adipose and cellular atrophy, with retardation or temporary arrest of growth. Now, it will be noted that in order to relieve intra-articular pressure the patient has the leg flexed to a considerable degree. The tissues covering the capsule are œdematous and dropsical, and feel boggy and non-resistant. The synovial membrane is greatly thickened and distended. The patient has the general appearances of strumor. He is pale, emaciated and badly nourished. When the disease is limited to the synovial membrane, the effusion will be considerable. This may be purely serous, sero-purulent, a sort of a grumous mass of pea-soup consistency, or it may, through pathological changes, have acquired a gelatinous consistence. Besides, when not disintegrated and absorbed, in time its residue will ossify and serve as a cement in effecting bony anchylosis.

In some cases, there will be extensive inflammation in the arthritic structures, without an excessive synovitis. There, as in other joint diseases of a tubercular origin, the presence of pain or muscular spasm is not always a reliable criterion; for, in tubercular caries of the epiphyses its advance may be so insidious as to escape detection until extensive damage has been done.

When the osseous elements of the knee-joint are the seat of an extensive tubercular invasion, all the circumjacent and enveloping tissues in the vicinity of the capsule participate. A low grade of inflammation supervenes which has a marked tendency to run into ulceration, so that, in time, the cartilages give way in places and the perichondrial or periosteal investment into which the ligamentous structures are inserted, sharing in the necrotic processes, break down and permit a luxation of the femoral condyles, its extent and direction depending on the situation and function of the detached ligaments. The synovial membrane seldom completely escapes when the tubercular process is well established. Now, the changes here noted during the varying stages and phases of this painful disease, are of infinite importance to notice; because by an intelligent comprehension of them we may be the better able to interpret their significance and check their progress.

It is apparent that the knee-joint is a passive agent. That it is largely made up—except the osseous parts—of non-vascular structures, as the tendons, cartilages and ligaments,—hence, one would assume that microbic action would be rapid and destructive in a part so defective in vascularity. Nevertheless, the contrary is the fact, for nothing can be more vascular than the lung, yet within its parenchyma tubercle works its greatest havoc. On the contrary, as a general rule, degenerative changes within the capsule of the knee advance slowly, as do those of a regenerative character, after the disease has spent itself.

The synovial membrane is commonly the favorite seat of incipient, tubercular infection. Being a serous membrane, it is highly vascular and molecular changes in the interstices of the lymph follicles are rapid and marked. Invariably, when it is occupied by inflammatory changes, these are transmitted through it by the absorbents to the superjacent structures.

The effusion in tubercular synovial inflammation, primarily, is purely serous, may undergo various mutations: purulent, gelatinous, fungoid, caseous or calcareous, the various phases of disorganization being associated with certain well-known clinical peculiarities. The more common termination of synovial effusion is the absorption of the primary secretion, or final disintegration, fatty softening, liquefaction and ultimate absorption of the residue. When, after synovial effusion, purulent or puruloid changes set in by the pressure of the contained acrid, irritating quality of it, granular, surface changes begin in the serous layer of the capsules, which by hyperplasia and interstitial infiltration develop into large, irregular shaped fungosities, which may stuff up the synovial space after all liquid effusion has disappeared.

The bone lesions are the most serious of all in knee-joint diseases; for, with the entire escape of the osseous structures in this malady, a useful limb may yet be preserved and the case is not apt to pursue such a chronic course.

The marked disproportion between the joint and the limbs above and below is more apparent than real; for, with inaction, the limbs quickly waste, while the swelling at the seat of morbid change remains, the contrast becomes all the more striking.

White Swelling.—The genuine tubercular osteo-arthritis, or synovitis, is a disease of great chronicity and usually passes through many painful stages before its course is arrested. In children it is a self-limited disease and will usually, in time, undergo spontaneous arrest, provided the powers of life can resist it until its march has ceased. I believe it very rarely ends in the loss of life, and that those who have been the victims of tubercular osteo-arthritis in early life, after adult years are attained, are mostly hardy, vigorous and energetic.

In the knee as in the hip or other joints, we may meet with every phase of tubercular infection, and we may find one or many of the structural elements of the articulation singly or simultaneously attacked. The disease becomes serious in the knee-joint only when the cancellous ends of the bones become affected and the disease extends beyond the capsule, involving the periosteum. This is not a common event, as the microbes of this malady manifest most frequently a preference for the periosteum or the non-vascular structures, as the cartilage and ligaments.

In the primary stages of tubercular arthritis at the knee, beyond certain vague symptoms, we have little definite evidence of the precise organic changes within the capsule until synovitis is present, and the periarticular elements exhibit evidences of pathological changes.

ANKLE-JOINT DISEASES.

This articulation in many respects bears a striking anatomical resemblance to the knee. Its articulating surface is very superficial, and like that above, is powerfully supported by numerous tendons. Its ligamentous supports, though numerous, are subordinate to muscular action through the medium of their tendinous termini. This is well demonstrated in talipes. This joint not only supports one-half of the body in standing, but it also must bear the body's entire weight. Yet, notwithstanding the constant jars, concussion and strains which it must endure, it is less vulnerable to pathological processes than the two other articulations considered.

The malleoli which wall it in laterally being mainly composed of dense, compact tissue, are seldom seized upon by tubercular infection. Where we do find this pathological process invade this joint, it will usually occupy the synovial membrane, cancellous head of the astragalus and extend downward into other tarsal bones.

When a serious phase of strumous disease is lodged in this articulation, we will find the foot extended on the leg, with the integument and cellular membrane of the former swollen and œdematous. The pathological changes in this situation in bone, synovial membrane or cartilage are essentially the same as those located in other joints.

TREATMENT.

The treatment of diseases of the three principal articulations of the lower extremities may be divided into constitutional and local, tentative and radical; all being dealt with on essentially the same principles.

Constitutional remedies will be resorted to when the pathological changes appear to have arisen from certain specific morbid influences, as gout, rheumatism, syphilis, malaria, gonorrhœa, or neuralgia.

That arthritis may arise from morbid conditions of the economy no one can question; nor will anyone deny that when this cardinal fact is understood, relief may not only be promptly effected, but simple measures may be instituted with a view to prevention. A failure to recognize the frequent constitutional or specific ætiological factors often operating in joint maladies may terminate disastrously to the patient whose condition, in consequence of misdirected therapeutic efforts, has not only not been relieved, but perchance greatly aggravated; and a temporary, trivial, functional affection has been made the groundwork of a condition sure to end in leaving the patient a cripple. Accordingly, in all cases of joint diseases of an acute origin, particularly, we must first search for systemic influences, malaria, rheumatism, or hereditary syphilis. The clinical symptoms of each of these maladies are usually quite clear and distinct, though they may blend with each other or others in many particulars, but so vague and imperfectly defined as to render little aid in diagnosis. When, then, we have reasonable grounds for suspecting that inflammation in, over, above, or below the immediate arthritic area is of a systemic origin, the patient should be kept in bed or on a lounge in the house, at any rate, and internal remedies plied with care and persistence until we are quite certain of the true character of the local changes.

At the hip-joint, mistakes will be most often committed. In the congestive or inflammatory conditions occurring at the hip, of the group here defined, in association with

internal remedies, local applications will serve useful purposes.

There unquestionably is a large number of joint affections of an hysterical, cerebral, or pyschological origin. The subjects of this neurotic class are usually anæmic, badly nourished, and have frequent moody, morose spells. Hence, morbid, molecular changes within the skull, in the brain substance, it is fair to assume, may, by reflex irritation, make themselves manifest in some distant region of the body.

From the obscure character of many painful affections in certain groups of muscles acting on joints and often exclusively limited to an articulation itself, in which, although severe pain and an infirmity obtains, yet there is no constitutional disturbance, no local, perceptible, tangible, morbid changes at the root of the trouble, so that they are very probably of a cerebral origin. There are two fundamental essentials necessary in the successful management of this group. To begin with, the patient's full confidence must be secured, or all our efforts are futile. You must make an impression. Sometimes this impression may be mental, again physical. It may be pleasant or painful. Hence, some of those crippled have been limbered out by an injury, a fall, or a violent concussion of the body, by a great fright, by sudden emotional effects, as surprise or joy. Hypnotism, mesmerism, and other occult phenomena have been successively invoked in these cases with varying results. No hard and fast lines can be laid down for the management of those arthritic neuroses. The greatest difficulty often consists in recognizing their true character.

The treatment of tubercular diseases of the joints and their over-lying parts has, since the dawn of medical science, seriously occupied the minds of practitioners. Its clinical features have been profoundly studied and thoroughly comprehended for ages. It was well known to commonly develop in connection with a well marked, constitutional cachexia, to pursue a very chronic course, and, finally, cease spontaneously after passing through some of its many various stages. It was not known, however, that its pathological basis was identical with tubercular meningitis of infancy and childhood, and pulmonary tuberculosis in the adult; that the germ of one was common to all.

Many teachers who had heretofore loudly proclaimed the invariable, traumatic origin of joint diseases *have been* suddenly silenced by the advent of the new doctrine. Sanguine, indeed, were all that at last the mystery was solved; and henceforth the management of this class of cases, conducted on strictly scientific principles, must always lead to no other than prompt and permanent cures. So that, almost at once, the moderate conservatism of the past was replaced on an extensive scale by radical and sanguinary methods. Joints were ruthlessly opened, scraped or wholly swept away by the blade and saw. Time was taken by the forelock and a local, tubercular lesion in the articulation of the child was as effectually eradicated in as many weeks as it heretofore was in years. Time, which is a great leveller, has, however, demonstrated that there is not so much in the bacterial theory as was first hoped; that it has been an *ignis fatuus*, the flash of whose light may often be better ignored.

It was discovered that those microscopical mites may lie dormant in the tissues for years; that at their worst they have but a life limit, or may be, in morbid processes, more rapidly devoured by the phagocytes than they can multiply. Those larger incisions and extensive resections, too, have been followed by a fresh infection at the seat of the operation, and even when this is not the case, so much shortening or deformity may result as to have the patient many times much worse than if nothing at all were done for him. Besides, there is a large element of danger in their performance, and the melancholy end, of not a few, has been a consecutive amputation or death.

Accordingly, we are practically driven back to the old lines and hence, as a matter of stern truth, the cardinal features of the underlying principles as promulgated in the early part of the present century by the great masters of the surgical art, must constitute our chief guidance in the treatment of those maladies to-day.

There can be but little doubt that in many instances the tubercular foci are limited to the soft parts outside the capsule and primarily involve neither the head of the femur nor the cotyloid-cavity. In these situations the infections may undergo spontaneous subsidence or advance to suppuration and cease. It is only when we are assured by the history of the case and the physical signs present that the bony floor of the acetabulum or the articulating head of the femur is involved by tubercular osteitis or osteo-arthritis that we are quite certain of the presence of a malady whose course is usually tedious, painful and destructive.

Now, what shall the treatment be in cases of osseous tuberculosis? Should it be mechanical or constitutional, or both? In mild

cases bodily rest, or rest in bed, and means to combat local inflammatory processes should be employed. Unless there be great intra-articular pain relieved only by traction, then no sort of extension should be employed, as a few weeks or a month's rest in bed may in itself suffice. In very serious cases of tubercular osteo-arthritis, not only good judgment is necessary, but skill and experience. Here, a knotty question of treatment arises, for our patient has a chronic affliction, and the measures instituted for his relief should be directed, not only with a view of effecting temporary relief, but for the purpose of securing as much functional utility and as little deformity in the limb as possible.

A recent writer[1] in an able brochure, asks the pertinent question: "When shall we discontinue mechanical treatment, in cases of hip-joint diseases?"

I would modify it by inquiring; "When should we commence the employment of mechanical means, in hip-joint diseases?" Should we employ any sort of apparatus at the outset? Certainly not! My own experience leads me to believe that orthopædic appliances at the present time are too frequently and indiscriminately resorted to, and that by this abuse much harm is being done. The best that any sort of apparatus can do is to prevent motion of the joint. But the complete and prolonged arrest of motion in the articulation of a child means temporary cessation of growth of the limb. No sort of mechanical adjustment will effectually secure complete fixation of a limb without considerable pressure of the soft parts and of the main blood vessels. Hence, mechanical appliances should not always be resorted to in the early stage of disease at the hip, nor ever, except by those skilled in their use. Should they here be employed as a prophylactic measure? I believe that only in very exceptional cases do they serve as an effective preventive; and that where they have appeared to have served the purpose the disease was not of a serious character. Orthopædic appliances serve an invaluable purpose as a means to early locomotion in chronic cases, but if they are worn too long, or are improperly adjusted, the patient, without question, would recover with a much better limb if none whatever had been employed. The firm, smoothly applied spica bandage, serves a valuable purpose in the early stages of hip-disease. Free leeching, the actual cautery and vesicants, each serve a most useful purpose in given cases, both to relieve pain and moderate inflammation and by stimulating the absorbents. When the head of the bone or the annular rim of the cotyloid-cavity has been destroyed by necrosis and serves to perpetuate an exhaustive suppuration it must be freely removed; great care, however, being observed to preserve the periosteum and the muscular attachments. In superficial necrosis with no serious local or constitutional disturbances, we may safely rely on the economy in either wholly detaching or dispersing the residue by absorption.

The hip is often traumatized, particularly in boys, by blows, kicks, falls, or twists of the leg. I believe that a traumatism may be an active factor in causing *morbus coxarius* proper. But, it is probable that it is very rarely so; for there are very few country-bred boys who do not often injure their hips by falls, yet, with the most intractable of them, this disease is very rare. One must be guarded, nevertheless, in prognosis, and watch the case diligently, if of traumatic origin, before applying any sort of mechanical contrivance. Swelling, sensitiveness and distortion often rapidly follow a severe contusion, or sprains at the hip: and if their true character be not recognized early, it may be confounded with serious intra-articular trouble, and be treated on wrong principles. This is the class of cases, *par excellence*, in which immediate, permanent fixation by any sort of plastic material, or other mechanical contrivance may be followed by unfortunate results.

It is clear then, that while rest of the injured part is a fundamental essential, it should be of a temporary and intermittent description; in other words it must be physiological and not mechanical. Indeed, so serious are the consequences of protracted fixation to the ultimate functional utility and strength of the growing limb, that the cases demanding its employment must always be of a grave and threatening character.

For myself, in a general way, in these pathological conditions, traumatic or otherwise, I think the safest course to pursue, is to be content with keeping the patient quiet in bed in the beginning, and if in doubt await events.

This may seem a reprehensible course, for it may be claimed that valuable time is lost when mechanical treatment might alone have arrested the morbid action in its incipiency. But, in traumatism of the hip, not involving dislocation or fracture, everyone, I think, will admit that rest and simple remedies will suffice, while, if tubercular, interstitial infection is the trouble, a short delay in the adoption of orthopædic appliances can work no evil.

[1] Dr. N. M. Schaffer, *N. Y. Med. Jour.*, *Nov.* 13, '91.

The treatment of disease at the knee-joint is to be managed on essentially the same principles as that of the hip, but as this articulation has very large articular surfaces and is very superficial, radical measures have been, and are still resorted to, for the relief of its deformities and diseases. Heretofore, the practice most in vogue, was, to depend on local and constitutional remedies, mechanical appliances, and time. Results occurring from this line of treatment varied from partial or complete restoration of function, to anchylosis, or amputation. Latterly, however, acting on the assumption that tubercular foci in this situation may give rise by diffusion to constitutional infection, and, besides, taking advantage of the security against consecutive inflammation and suppuration which modern surgical methods offer, the synovial-membrane has been freely opened for divers purposes, and not infrequently the whole articulation swept away by resection. It has been amply demonstrated, however, that the invasion of vital organs is not necessarily seriously threatened by a local tubercular action. The incision of the capsule for the relief of great tension, moderate erosion and drainage, is, in my mind, a substantial improvement. However, they are but palliative measures which must be employed under pressing circumstances, and even then, only when every possible precaution has been taken against extraneous taint.

The great controversy has been on resection of the joint. Why carry a patient over months or years of suffering, and be content, perchance, with nothing better than anchylosis and deformity, when the malady may be cut short and the distortion obviated by radical surgical intervention?

On superficial examination this question would seem unanswerable, but when we submit the subject to the rigorous scrutiny we discover that the consequences following resection are often unsatisfactory, or worse; that it cannot be regarded as a cure of joint disease, for the simple reason that it leaves no joint to cure. And further, in growing children, that class in which it promised the best results, its application is most unfortunate on the growth and usefulness of the limb.

A resection of the knee-joint means practically its total destruction, *i. e.* the whole of the synovial membrane, the patella, the ligaments, the articular surfaces of the condyles, and head of the tibia are cut away in order that the sawn surfaces of the bones may be brought together and secured. Now what becomes of the immense hiatus remaining after the complete extirpation of all the cartilage, the ligaments, and osseous structures of the joint? Certainly a large gap remains. It is filled in with practically nothing if we exclude a thin layer of connective tissue and usually sufficient osseous substance to cement the divided ends of the bones together. There is, then, indispensably connected with resection, shortening, which proportionally increases with the rising and maturity of the body. But this is not all, the muscular fasciculi of all the hamstrings and those of the quadriceps extensors reduced for all time to a state of inaction, atrophy and degenerate, so that there follows a great diminution in the volume and strength of the thigh.

The substitute remaining for that once powerful, mobile joint is practically nothing but the glued-together ends of bone and an investment of integument.

An angular deformity, however, has perhaps been removed. True, but a perpetually straight lower limb is abnormal, as the leg is almost never long retained fully extended on the knee except in the standing attitude. Besides for purposes of utility and strength the flexed limb is by all odds much more serviceable than one anchylosed in the extended position.

When, nevertheless, there has been extensive destruction of the ends of the bones, the ligaments have given way, and the cartilages are broken down, the propriety of a resection then—if we may so designate the complete clearing away of necrotic structures—is an open question.

When these destructive changes have been consummated, one may hesitate between leaving the leg intact and favor fusion of what remains of the condyles and the head of the tibia, or an amputation. My own opinion is that the leg should be spared if possible, and the weakness at the seat of the knee-joint compensated for by a mechanical support.

During the past five years or more many European surgeons have been treating tubercular affections of the lower joints by intra-articular and interstitial injections of solutions of the various inorganic salts, hoping to secure by their action the destruction and absorption of the bacilli. Many cases have come under my observation recently, in which these injections have been employed. No doubt, when proper precautions are observed, this method in properly selected cases serves an important purpose, but we should be careful that in certain cases those pungent liquids do not light up an active and uncontrollable inflammation, and thus greatly aggravate a

case which was possibly making slow, but steady progress towards recovery.

At the ankle-joint tubercular infection is not of so frequent occurrence as in the hip and knee, though, when it does attack this articulation, its progress may be of an alarming rapidity. I have had a case under observation in which, from the first manifestation of osteo-arthritis at the ankle to the complete disorganization of the bony structures scarcely five weeks elapsed. The ankle-joint, like the knee, having no muscular investment is quite superficial for direct surgical treatment, but as with the former, orthopœdic appliances should always be resorted to in treatment rather than surgical intervention by sanguinary methods; for a solidly anchylosed ankle-joint may serve a most useful purpose throughout life, with little, if any impediment to locomotion, or apparent deformity. In this situation where the main tarsal supports have broken down by interstitial necrosis, and no active efforts at compensatory regeneration in their periosteal envelopes are evident, then an amputation is imperative; for without the astragalus and os calcis the remaining parts will be a source of misery and a useless appendage.

ANCHYLOSIS.

Moderate and complete, false or true anchylosis is one of the sequelæ which may result in varying degrees after injuries or diseases which involve the muscle bones and joints and restrict their free action. Our efforts should, in all cases in which this is feared, be first directed towards preventing permanent stiffness. This can best be accomplished by massage, early motion and bandage pressure.

Anchylosis is the *bête noir* of immobilization. How to preserve quiet in a diseased joint for a great length of time without seriously impairing or destroying its utility is a difficult problem. The mere fact that protracted fixation of an articulation induces no destructive, pathological changes in the joint itself, is no proof of its immunity, for in many of the most hopeless cases of anchylosis of the knee which have come under my observation, are those in which the sole difficulty was confined to the muscles, muscular sheaths, tendons and nerves, far away from the crippled hinge.

After traumatisms and moderate attacks of non-articular or muscular rheumatism, neuralgia or other vascular or neural affections, giving rise to pain and a tendency to keep the limb in a fixed position, an anchylosis may follow, which if its true, pathological character is not realized early, serious detriment may accrue to the functional use of the limb, or appliances may be adjusted which are rather responsible for the condition than the injury or malady itself. Hence, the vital importance in affections of every description which involve joints, whatever may be their nature, of instituting such exercise or motion as is compatible with physiological rest, with a view of preventing, (or if stiffness must result) of limiting its degree as far as possible.

Anchylosis is occasionally amenable to treatment according to its nature. For bony anchylosis, in which there is complete fusion and solid ossification of the articular surfaces, nothing can be done. Though, of late years, articulations have been resected with varying degrees of success. This, however, is not restoring motion in the joint, as the latter has been sacrificed. Muscular anchylosis, when fibrous changes have occurred in the fasciculi, and throughout the entire planes of the muscle and they are bound together, contracted and atrophied, is as irremediable and always more unfortunate than osseous. There is a species of limitation of action in a joint that might frequently be obviated altogether.

False anchylosis, so-called, is always more or less readily remediable. It frequently follows injuries and transient inflammation in or about the joints. If neglected, it may result in a permanent crippling of the limb. Judiciously applied force usually overcomes it, though here as in other species of anchylosis, one must proceed with great prudence in order to avoid injury to the nerves or blood vessels, or fracture of the bones. Frequently tenotomy or division subcutaneously of adventitious bands is a most valuable accessory in many cases.

Surgical history notes that singular class which moderns have designated phychological —those hypochondrical, hysterical, anæmic young women who have painful, tender joints which became so without any apparent cause. We find no evidence of organic change in the articulation. Medicines and topical applications have no effect and the crippled state remains. But a mental or physical impression is suddenly made, she throws aside her crutches and walks away cured. These are the cases in which the old-fashioned bone-setters would always have it that "the bone was out," and in which, by the abrupt and violent application of a twist and squeeze, torturing pain is for the moment inflicted; the patient recovered from the sudden shock, she was quite confounded to find

herself cured. With this class of joint maladies no anæsthetic should be employed. The practitioner, after having carefully examined his case, must speak with a confident assurance. When he takes the limb in hand, he will find that there is commonly a certain group of muscles hyperæsthetic, which, on any movement of the joint, gives rise to great pain. A firm, sudden and compound motion must be made, when we will usually feel adhesions give way under the hand as force is applied. I never put on any sort of dressing after the manipulation, but simply tell them that the more they exercise the joint the more thorough and permanent will be the cure.

Much might be said of the pathological changes which are mainly confined to the neighboring bursæ, the tendon insertion, the thecal envelopes, the medullary spaces and periosteal tissues, adjacent to and essential constituents of the articulations; but the object herein undertaken has been to call attention to and re-awaken interest in the study of the articular affections in the lower extremity so common in early childhood without any attempt at an analytical *résumé* of the latest notions of microscopical pathologists with regard to their minute elements.

CONCLUSIONS.

It may be said then in a general way that the maladies at the hip, knee and ankle joints in early childhood are functional and organic, intra- and extra-articular; that tubercular affections of the synovial membrane, the arthritic elements and the heads of the bone though sometimes tedious in their progress are self-limited. In their milder forms requiring little, if any, mechanical fixation of the affected joint. The premature adaptation of any sort of orthopædic appliance may result in serious ultimate consequences to the utility and strength of a limb; for enervation atrophy, contracture and fatty degeneration of muscle, always follow the long-continued, forced inaction, and absolute arrest of motion in an articulation.

Mechanical apparatuses when applied at the right time, judiciously selected and skillfully adjusted, are of infinite value; but when these conditions are not faithfully complied with, then the patient's chances are much better without them.

There is yet good ground for very strong and emphatic objection against resection of the knee-joint; for the total mechanical destruction of a joint is not a cure in any sense; hence, it can be justified only when disease has so far disorganized the osseous and osteochondral structures that amputation becomes necessary, as an anchylosed knee-joint is a hundred-fold more serviceable through life than no joint at all.

Caution must be always observed that functional is not confounded with organic or extra-articular joint diseases, as early fixation employed extension of a given limb arrests its growth. Besides, with moderate articular motion and muscular movement, full restoration will be much more rapidly attained than by any sort of mechanical therapy.

In recent extra-articular anchylosis, in order to derive the most prompt and permanent benefit from the liberation of the adhesions, the force should be cautiously but suddenly applied *without* an anæsthetic.

The term "hip-joint disease" should be rejected from surgical nomenclature as a term too vague and misleading. Maladies at the hip should have a classification based on precise and distinct pathological changes. By abiding this antiquated term there can be no doubt that not infrequently for a trivial inflammatory state of the soft parts, measures have at times been instituted intended for dealing with the more serious intra-articular disease.

Finally, in each and all of those pathological conditions at the hip, whatever be their extent, we should not lose sight of the cardinal fact that they all arise either from unsanitary surroundings, improper dieting, inheritance or malnutrition; hence, the root of these maladies must be reached by hygienic changes, proper food, freedom and the open air, and such medicines as will best combat inherited tendencies and favor the assimilation of a nutritous diet.

It will be noted here, that in the category of remedies for joint lesions nothing more than an indirect reference has been made to antiseptics. Antiseptics, except for purposes of purification of a sore or a wound in a joint, though they promised much, have been disappointing and serve scarcely any purpose in the treatment of affections here considered. —(For discussion see Society Reports, p. 341).

CARDIAC DROPSY.

Dr. Furbringer (*Il Raccoglitore Medico*, No. 15, 1891) uses the following:

℞

Lufus. folior. digitalis (2 p.)	....grammes	150.
Caffein. citrat	"	2.
Tinct. strophanth	"	5.
Liquor potass. accetat	"	60.
Succ. glycorrhizæ	"	5.

Sufficient for two days.

It may be pushed until the diuresis rises to 5 quarts a day.

THE TREATMENT OF DIARRHŒA IN CHILDREN.*

By DR. FLORAND,
PARIS, FRANCE.

It is not my intention to discuss the arduous and difficult question of infantile diarrhœa, nor do I propose to give any classification. I simply wish to consider the treatment of the disease *apropos* of five cases which I have observed recently. I will call attention to the treatment which seems to me the most proper to employ in certain cases of diarrhœa in children. One of the observations was a case of choleriform enteritis; the remaining four may be classed among the true diarrhœas, or better perhaps among the infectious gastro-enteritis occurring during the weaning period. Two of these cases I studied with Dr. Hutinel, to whom I first showed the especial method of treatment which I am about to relate. The other three were purely personal observations.

This treatment, first put into practice in Germany and communicated to us by Professor Grancher, has been used recently by Hutinel, by Dr. Sevestre at L'Hopital Trousseau and by me at L'Hopital des Enfants. We shall see what the results have been at the hospital, and study the reasons why such results have differed from those seen in private practice.

Case I.—X——, 15 months old; nourished at the breast; was weaned at the eleventh month, and afterwards fed, for about fifteen days, on milk, farinaceous articles, eggs and vegetable soup. The appearance of eight teeth was attended with no trouble whatever. On the 27th of September the child was attacked with diarrhœa, which the mother attributed to the cutting of the two upper molars.

I saw the child for the first time on the 2d of October. The diarrhœa was exceedingly marked; the stools were abundant, fetid, a little glairy, of a slight greenish color and of a decided grumous appearance. I advised the exclusive use of milk, and the employment of a mixture composed of salicylate of bismuth, lactic acid and paregoric. I again saw the child on the midnight of the 3d of November with Dr. Marcy. The little patient had had since the day previous twelve or fifteen stools, accompanied with vomiting. The passages were exceedingly fetid, and consisted of undigested milk and a large amount of liquid.

The child continued to suffer at intervals; his mouth was a little dry, and the rectal temperature 39° C. Enema with laudanum diminished neither the diarrhœa nor the pain, until a mixture of bismuth was ordered.

The child was placed on a limited diet on the 4th of October. On the 5th vomiting ceased, but the diarrhœa and the swelling of the abdomen continued. The little patient was restless, excited and peevish.

On the 6th there was a slight amelioration and the child was given some teaspoonfuls of broth. By evening the diarrhœa, the swelling of the abdomen, the pains and the general excitement returned.

On the 7th a consultation was held with Dr. Hutinel. The temperature of the patient was 39.5° C., pulse 130. The abdomen was much swollen; the tongue very dry, and the thirst intense. The child had had five stools of a dark, greenish color and fetid, and had not urinated. The skin was dry, and the child was so emaciated and weak that he could hardly support his own head. He constantly gave evidences of pain, which was pronounced at the moment of going to stool. All the other organs were apparently intact. Dr. Hutinel advised an absolute liquid diet (albuminous water and iced grog), a bath at 34° C., four centigrammes of calomel to be administered in the course of four hours, and washing out of the stomach if the symptoms persisted.

The night being passed by the patient in a restless manner, and the tympanic condition of the abdomen continuing, two glasses of hot water were ingested into the stomach. On the morning of the 8th of October this procedure was repeated with the aid of a gum sound, No. 13, provided with a funnel. After the operation, which was performed without the least difficulty, the child rejected a flocculent, slightly brownish and grumous liquid. After the washing, calomel was administered in the same doses as on the previous day. For the first time in six days the child slept that afternoon for seven consecutive hours.

In the evening the patient was less restless, but complained a great deal. A second washing was instituted on the next morning and this was followed by a calm sleep of six hours.

On the previous day, after the washing of the stomach as described, the child had only two greenish stools, but these were thick. The patient also suffered evidently from bad dreams. On the 9th of November the bowels were moved in the evening by means of an enema.

On the tenth the child appeared exceedingly calm, had passed a good night, his tongue was less dry, his belly less swollen and less painful, his skin moist, and had urinated abundantly. His stools were greenish and but slightly fetid. The child was given three drops of hydrochloric acid in sixty grammes of grog. On the following days the bowels had to be moved by means of enemata.

From the eleventh day alimentation was administered with great caution; 250 grammes of ass's milk in twenty-four hours was well tolerated, after four days of an absolute liquid diet. From the 14th the child was nourished with sterilized milk. Without any other untoward symptoms our little patient recovered with extreme rapidity.

Case II.—Andre X., 22 months old; nourished primarily at the breast. After the age of nine months he was given milk, and after the twelfth month, eggs, bread and vegetable soups added to the milk. The child had sixteen teeth and suffered relapses of sickness dependent upon the period of lactation, and afterwards from slight troubles of digestion, fetid diarrhœa and vomiting, all of which symptoms yielded rapidly to a light diet and a light purgative.

* From *La Medicine Moderne.*

These symptoms again appeared after eight days with such tenacity that they resisted all treatment, notwithstanding the observance of a strict diet. The child grew thin and weak; his thirst became pronounced and his tongue somewhat dry.

I decided on the 13th of November to wash out the stomach, which I did with Vichy water, following this by the administration of five centigrammes of calomel in doses of centigramme every hour.

The liquid diet was maintained until the 15th. The vomiting and the fetid diarrhœa ceased on the 14th. The alimentation, consisting of broth, and afterwards of soup, was resumed.

On the 22d of November, the child was placed on his old habitual diet. The troubles of digestion did not reappear and the child made a rapid recovery.

Case III.—John ——, aged 9 months; was from birth nourished by a mixed diet consisting of the mother's milk and carefully boiled cow's milk. On the 17th of October, he was attacked with symptoms of a choleriform enteritis; vomiting and abundant diarrhœa, which were increased with the ingestion of food. The stools were fetid and made up chiefly of undigested milk and a flocculent, clear liquid.

The urine was scanty, almost wanting. The child manifested a worn-out appearance, was greatly emaciated, notwithstanding that the diarrhœa had been only of a forty-eight hours' duration. The eyes were sunken and there was a pinched expression of the face. His extremities were cold, and his rectal temperature was only 38.8° C.

I ordered all alimentation to be stopped, and I then gave three centigrammes of calomel and grog.

The symptoms persisted. I then, on the 18th, washed out the stomach with hot water, using a No. 8 sound, and readministered the calomel.

Vomiting ceased, and from sixteen and twelve daily stools which the child had on the two previous days, the number was reduced to four. The little patient passed a bad night; so I again washed out the stomach on the following morning.

The exclusive alimentation with the mother's milk was cautiously resumed on the same day, and five days afterwards the child was placed on the old mixed diet, substituting the boiled with sterilized milk. No bad symptoms returned.

Case IV.—Jeanette X——, 6 weeks old; weighed at birth, 3700 kilos; was subsequently afflicted with imperfect nourishment. Her digestion was bad and laborious. She rejected the milk soon after she was taken from the breast; yawned frequently, and would cry without apparent cause. She had alternations of increase and diminution of bodily weight, and on the 6th of December, that is six weeks after birth, she had only gained 400 grammes. Her third nurse seemed to be in the best condition as to health, yet the child began to have every day from five to six stools of a greenish color, or turning green soon after their expulsion. They consisted chiefly of undigested milk.

The symptoms were somewhat ameliorated by the use of lime water, by Vichy water and by lactic acid; but as the child did not gain much in weight, and as the stools became frequent, sometimes of a green color, and causing by their presence an erythematous eruption about the buttocks, I advised the parents to let me wash out the stomach of the child. The operation was executed with comparative ease, and through a No. 8 sound I introduced a half-glassful of hot water.

The procedure was followed by the administration of two centigrammes of calomel in three doses.

The alimentation was continued with no other modification than a slightly prolonged interval between the sucklings.

After this operation the stools became regular (two a day). They were but slightly liquid and the greenish coloration of them was only seen two or three times and only once during the day.

Case V.—Louise F——, 30 months old; was nourished at the breast by not a very good nurse. Her digestion has been imperfect, and during the suckling period she suffered from attacks of diarrhœa. Her alimentation has been attended to with a good deal of care by her own father, who is himself a physician and a keen observer. For a long time the child has been placed upon a diet of boiled milk, to which were added a little soup, lactated flour and eggs. On the appearance of every period of dentition, she was troubled with marked troubles of digestion. The appetite at present is capricious, and alimentation sometimes is by no means an easy task.

On the 2d of November, on the rupture of the small molar teeth, the child exhibited a marked loss of appetite, followed by a fetid diarrhœa; and on the 8th of the same month, the diarrhœa was accompanied with vomiting, likewise fetid. The child had meteorism, the abdomen being slightly painful on pressure. She was much depressed, notwithstanding that there was a slight rise of temperature. Her extremities were cold, and after a few days she became much emaciated.

The fetid vomiting and diarrhœa continued during the 9th and 10th. The abdomen was somewhat swollen. The general condition was worse. Dr. Hutinel saw the child on the evening of the 10th, and advised a washing out of the stomach, to be followed by the ingestion of three centigrammes of calomel and a liquid diet (albuminous water and grog).

I practiced the stomach washing the same evening. It gave rise to the rejection of a large quantity of extremely fetid matters (milk and lactated flour), and I found it necessary to repeat the operation several times in order to completely clean out the stomach. During the procedure the child had also a fetid stool. There was a condition of amelioration during that evening and on the day of the 11th, when the child ceased to vomit and her abdomen became less tympanitic. On the night of the 12th, the little patient became worse again and was restless and peevish. She asked frequently for drink. Her abdomen became swollen and somewhat painful.

On the morning of the 12th, I gave my little patient a new dose of calomel. She had three green stools, somewhat glairy and still fetid. One of these had some bloody shreds. On the advice of Dr. Hutinel, I practiced during the day a second washing out of the stomach. The water ejected was slightly foul, somewhat flocculent and contained some brownish shreds. Part of the hot water remained in the stomach. On the 13th, the child appeared better, did not vomit and had no stools. She was given a few mouthfuls of broth. In the evening the meteoric condition of the stomach returned and the child became restless. I again administered two centigrammes of calomel, and the child was once more placed on absolute liquid diet.

It was afterwards necessary to produce movements of the bowels by means of enemata. Alimen-

tation was resumed with extreme caution, administering small quantities of raw meat well chopped up and afterwards broth and sterilized milk.

In about eight or ten days the patient resumed her old diet. The child, during the first days of convalescence, exhibited a voracious appetite. This intense hunger soon ceased and was replaced by an appetite less pronounced, but better than had been manifested by the child since her weaning. It was, indeed, sufficient to rapidly restore the lost energies, and principally the considerable weakness produced by this sort of infectious gastro-enteritis difficult to classify.

These five observations present such a peculiar interest that they need some consideration. Every child attacked by diarrhœa during the weaning period, due to a faulty nutrition, the diarrhœa being accompanied or not by vomiting, should have the benefit of stomach-washing and be subjected, at the same time, to the internal use of calomel and a diet of albuminous water and grog. The washing out of the stomach may be practised twice or oftener, according to the case, with hot water or Vichy water. The intestines should also be cleansed out by means of enemata of hot water slightly borated, especially if the evacuations are insufficient. The child must be kept in warm media, the feet well wrapped up and the abdomen well padded. If the temperature is elevated a warm mustard bath, at 32° C., is useful. If there is pronounced tympanites a poultice should be ordered to be carried over the abdomen.

The tympanites, the pains, the vomiting and the diarrhœa, whether they co-exist or one or the other phenomenon should come on separately, are all indications for the employment of the stomach-washings, the internal administration of calomel, and the subjection of the patient to the diet indicated.

After the disappearance of the symptoms, alimentation should be resumed with the greatest care. This should consist either of ass's milk, broth deprived of all fat, and small quantities of sterilized milk. If these measures should fail, the ingestion of raw meat, according to the method of Trousseau, should be resorted to. If at the beginning of such alimentation there should appear green stools, a little lactic acid, or from four to five drops of hydrochloric acid, should be administered, The washing out of the stomach in children is easily practised. The younger the patient the more simple the operation. After placing a cork between the teeth or the gums of the child, as the case may be, a caoutchouc urethral sound, of a calibre proportionate to the age of the patient, and to which a funnel should be attached, is to be introduced into the stomach, the whole apparatus acting upon the principle of a syphon. The introduction of the sound generally presents no great difficulties, the operation being performed in the course of a few seconds. The sound being introduced, two glassfuls of hot water are to be ingested, this being soon followed by the expulsion of the stomachic contents. If the matters ejected have a foul odor, the operation is to be repeated twice or thrice; immediately after, the first dose of calomel, 1 to 2 centigrammes, is to be administered, which is followed by a second and a third dose, at intervals of one hour. Generally a single washing out is sufficient; two or three are sometimes necessary. Albuminous water and grog are to be given in tea-spoonfuls every 5 to 20 minutes, according to the degree of the thirst and to the dryness of the mouth.

Most commonly, good results are immediate. The child soon after passes into a quiet sleep, the bodily temperature is lowered and the vomiting ceases. The evacuations, at first fetid, lose their bad odor and may even be suppressed. All the local and general phenomena are lessened or disappear entirely. The abdomen becomes less tympanitic and less painful. The restlessness and prostration are changed into a quiet condition of the system, and the reparation of the vital forces ensues through the effects of a refreshing sleep. The child begins to urinate.

The diet *per se* works wonders, and the little patient tolerates it for many days, provided it is composed of albuminous water and grog.

I may say that I have given, at the beginning of the disease, mixtures containing bismuth, paregoric and laudanum, which have sometimes attenuated the malady, but such medicaments have only acted as palliatives and were never sufficient to save the life of the little patient. It is unnecessary to recall the fact that diarrhœa in children has frequently a fatal termination. To be convinced of this it is sufficient to examine statistics of the terrible malady.

If the disease presents in hospital practice a greater mortality, this is evidently due to the fact that children are generally brought to the hospital in a weakened condition and are then subjected to a continuous re-infection. Besides, it is difficult to follow rigorously and carefully the treatment referred to. On the contrary, in children isolated and well taken care of in civil practice, the employment of this method of treatment is advantageous, as the results show in the cases reported, which cannot be considered as mere happy coincidents.

All these cases presented the most serious phenomena, and one of them was treated ac-

cording to other known therapeutic measures but without the least success. I hope, therefore, that new observations will permit me to study more fully the most precise indications for the treatment advocated, and to be able to give the reasons for the success obtained. Certain it is, that washing out the stomach removes from the organ all the toxic products which are contained in it and which are being constantly elaborated and absorbed in the intestines.

Calomel finishes the task, so to speak, begun by the stomach-washings, the action of that drug being antiseptic and purgative. It purifies and releases the intestines of irritating materials. Thus, by means of stomach-washings and the administration of calomel, a cleaned-out condition of the whole digestive tract, from the mouth to the anus, is brought about.

SCALDS AND BURNS.

By A. D. BINKERD, M. D.,
WEST MONTEREY, CLARION CO., PA.

"A burn is the most dangerous of all wounds," says the elder Gross.

Methinks I can still hear his finely modulated voice as he uttered this truism, and in my mind's eye still see his commanding figure and dignified manner while delivering his matchless didactic lectures in his palmy days, a quarter of a century ago, in the Old Jefferson. Like Abraham Lincoln, Dr. Gross, dead, still lives to challenge our respect, a worthy exemplar.

A burn may indeed be a most dangerous wound. Often has this fact been most sadly demonstrated. Whether a scald or a dry burn, the result may be equally dangerous. If one-fourth or one-third of the surface of the body be severely burned, we should make our prognosis with great caution. A mere hyperæmia of the skin extending over a considerable portion of the body, especially over the chest, may, and often does, result fatally within a few hours. When a severe chill convulses the form of your patient, be on your guard. It means mischief. I have seen acute pneumonitis destroy the life of a patient who had been apparently but slightly, and not at all dangerously, burned, death resulting within thirty-six hours. I have seen young men, in the prime and vigor of early manhood, walk unaided away from a wreck, talking hopefully of recovery from the effect of a steam bath or the hot water that had fallen upon them, become chill and cold in death within six hours. Truly, a burn is the most dangerous of all wounds.

A burn is also the most painful of all wounds. The skin is everywhere abundantly supplied with nerves; these coming in contact with a body having a temperature of 150° F. and upward, or 32° or less, assume an excessive irritation. The continuity of the skin being destroyed by a degree of heat much greater or much less than that to which the part has been long accustomed (for there is little difference between the effect of a burn and that of frost-bite) the nerves are despoiled of their integument, exposed to the air, disturbed in their functions, producing painful irritability. A small burn of sufficient intensity to produce vesication is often quite as painful as a deeper burn involving a considerable extent of surface. The resulting shock is probably much greater as a result of the greater burn.

The tendency to "run," and unwillingness to heal, have characterized a burn in all ages. The life of the patient has been not infrequently sacrificed by the constant drain upon the constitution resulting from death of the parts.

Pain and protracted suppuration are not the only evils arising from a burn. Danger to the usefulness of the parts after recovery, and unsightly cicatrices stand out boldly as important sequelæ to be avoided at all hazards or modified to the utmost degree. To accomplish this object is to be successful in the treatment of a burn.

A burn differs from an incised, contused, lacerated or punctured wound, being capable of imparting to the nervous system a more profound shock, which in some way modifies the career of the traumatism. Who does not remember the unsightly and unscientific pinning down of the chin upon the sternum, as the result of a severe burn involving these parts? With honest pride we can now state these things need not occur. The experience of twenty-five years has, over and over again, verified the statement.

It has fallen to the lot of the writer to meet a very large number of burns in the oil regions of Western Pennsylvania, from the close of the war down to the present time. These cases include every possible degree of severity—from the instantly fatal down through the long line of possible and probable recoveries. They include all ages and both sexes from the octogenarian to the babbling infant. I have seen the whole family annihilated—father, mother, and children, amid indescribable agony, but of very short duration. Everywhere and under all conditions

I have observed the effects of a burn to be the same. The treatment of burns now claims our attention.

We set out with the belief that a burn is a stubborn traumatism to deal with. In this particular we will probably not be disappointed. Having surveyed the extent and depth of the traumatism, and carefully marked the profundity of the shock upon the nervous system, observed closely the number and character of respirations and pulsations per minute, the presence or absence of thirst, also the tendency to chilliness (of the utmost pathognomonic value), you may now venture upon a prognosis. Here you will encounter the most vexatious disappointments. Suppose the burn is recent and of the extent of the palm of one or two hands, one-half the surface is in a state of hyperæmia, and from the other half the skin has come away in shreds with the garment. The wound is exceedingly painful. The patient can neither stand nor sit long enough to have any dressing applied. If the patient be an adult administer at once:

Morphia sulph.....grammes 0.033

Dress the wound with:

Glycerine..... .....cc. 30
Acid carbolic, fld. .....cc. 3

Incorporate thoroughly.

Saturate portions of cotton batting; cover the wound entirely; also finish the dressing with a roller bandage, neatly applied, but not too tightly. Make ample allowance for possible swelling. Above all be neat and clean in handling a suppurating surface. Your patient will now quiet down and show a disposition to sleep. See that he is kept quiet and let him sleep. Towards morning he will complain of acute pain of the burned surface. Decomposition of lymph has set in, the presence of matter is painful. Remove and burn all the dressing. With a basin of clean warm water and a fine brush remove every particle of lymph. Dry the surface of the wound by firmly applying bits of clean old, worn, cotton garments. Blood pours out here and there, and an angry, rebellious condition obtains all over the wound. Incorporate one grain of morphia sulph. with 2 or 3 cc. of tannic acid, and sprinkle over the surface. Then dress again with the glycerine lotion, and finish with the roller bandage as before. And let remain 8 to 10 hours before dressing again. Water may be given freely. Copious drinking followed by vomiting till death closes the scene, which I have sometimes witnessed, is only another evidence of the fatality of the burn. This is rarely seen after the first day.

We have now entered on the third day. The pulse is small and wiry, secretion from the kidneys scant and high colored. Appetite *nil*, tongue furred, and a bad taste in the mouth. We remove the dressing, a stream of offensive smelling lymph streaked with blood flows down and drops off the elbow. You need not ask the patient how he feels. You need but look at him to know that he feels sore in person and irritable in temper. How should he be otherwise with all the secretory organs in a state of torpidity? Woe to the luckless doctor who will venture an untimely joke at seasons like these. But happy the man who like the elder Gross or the elder Flint will enter into the sympathies of the sufferer while endeavoring to relieve the agony of both body and mind and thus challenge both his respect and admiration. The bowels are now thoroughly evacuated by a few doses of sal Epsom, the secretions reestablished, the appetite is reasserting itself. The character of the wound has changed, the transudation is less profuse and more consistent. Granules are springing up and struggling for continued life, many to be washed away by the excess of lymph, a few to survive.

The glycerine lotion has served its purpose. It is no longer applicable. The character of the wound has changed; this necessitates a change of dressing, one that is both soothing and astringent. What shall it be?

The following most unhesitatingly:

℞

Cera flava.....cc. 60.
Ol. olivæ.....cc. 600.
Acid. tannic.....cc. 30.
Acid. carbolic.....cc. 5.
Bismuth subnitr.....cc. 10.

Melt and strain the wax, keep it hot in one vessel while you heat the oil in another, when both are equally hot, (90° C.), pour together and stir, let cool gradually and stir continuously to insure uniform consistency. When of the consistency of apple-butter, add the tannic acid, then the bismuth, and finally, the carbolic acid. Continue the stirring process till the whole is cold. This, when properly made is a plastic substance which may be taken up with the spatula or with the fingers. It makes a sightly dressing and is not sticky, but is easily applied and easily removed. None of that nauseating and offensive smell, so common in the days of lime water and oil, can be detected where this unguent properly prepared has once been used.

How to apply a dressing to a burn is not known by everybody, even when you have the most potent remedy for good. Mother-wit and plain common-sense must be largely

relied on here, as in reducing a fracture or subluxation.

It is now the evening of the third day, though the character of the wound is somewhat changed, the effusions of sanious lymph is profuse, and in its state of partial decomposition is vile-smelling and painful.

How to proceed to dress is the next question. Do not lock up the secretions again by giving an opiate.

With a basin of tepid water, a fine camel's hair brush and a piece of fine old Castile soap, I remove all matter of every character. Remove all shreds of skin carefully with dressing forceps and scissors. Cleanse away every nidus or lodgment for the ever vigilant microbe. Dry the entire surface with patent lint, then sprinkle the part thoroughly with tannic acid and bismuth sub nitrate, equal parts. Cut your patent lint into strips one inch wide and of lengths to suit, 2, 3 or 4 inches, rarely more. With your clean spatula, or limber table knife, cover evenly one of the bits of lint to the required thickness, rarely to exceed two millimetres. Hold to the fire till the dressing is soft and warm, then apply gently but firmly to the raw surface of the wound. This imparts an agreeable, soothing warmth to the part. Continue rapidly applying one strip after another till the whole is covered—not only the denuded parts, but also all the hyperæmic portion. Then apply gently, neatly, and not too firmly, a narrow roller bandage, with the reverse turn to adapt it uniformly to any irregularity of the part. To the art of bandaging neatly the surgeon is largely indebted for his success. And so will you be in the successful treatment of these wounds.

Though the patient may be feverish, restless and irritable, it has often seemed to me that some soothing influence crept over him while I was at work—long before I had finished the dressing, the patient was locked in profound sleep, equally ignorant as to when I finished the dressing or when I left the house. This has happened to me so often, and with such uniformly good results, that I can safely and cheerfully recommend my method with the means described as *the* treatment for a burn.

The critic may say, "There are opiates in your dressing." I beg his pardon. Not a grain. After the first hour or two opiates are not applicable, or rarely so.

On the fourth day I find my patient refreshed and cheerful. I remove the dressing and find the character of the traumatism still farther changed. The angry appearance of the day before has subsided. The discharge is less profuse and of thicker consistency, "laudable pus"—as the elder Gross was wont to say—bathed the parts, beneath which healthy granules were springing up everywhere. I cleanse the wound thoroughly, as before, and dress in the same manner and with the same material with the same result. A few weeks will suffice for the treatment of a very severe burn, while as many months under the old methods would leave the patient disfigured and probably disabled for life.

In conclusion: 1. I insist upon the observance of the utmost cleanliness, twice a day if necessary. Remove all shreds of skin and all lymph.

2. I insist on cutting the lint on which the ointment is spread into small bits to insure perfect adaptation of the dressing to the inequality of the surface.

3. Observe and enforce the strictest rules of hygiene. Give the patient plenty of good, wholesome and nutritious food, of which milk should constitute a large part.

The above is the sum and substance of a quarter of a century of practical experience.

A CASE OF OVARIAN CYSTOMA.

By ARCH DIXON, M, D.
HENDERSON, KY.

Mrs. G., aged twenty-nine, married, mother of four children, youngest child two years of age, had not felt well since her last delivery, which was long and tedious. One year ago she noticed an enlargement, low down on the right side, about the size of an orange. Was not examined by any physician at that time. Enlargement grew rapidly, causing much pain and discomfort. On June 10th, I was requested by her brother, Dr. Thos. Bethel, of Pooletown, Webster County, Ky., to do abdominal section, and if possible remove the growth, the character of which he had not determined. On June 14, saw the patient for the first time at Robards, Kentucky. Diagnosis, ovarian cystoma. She was anxious for an operation. Assisted by Drs. John Young Brown and Arch Dixon, Jr., I proceeded at once to open the abdomen. A large quantity of ascitic fluid surrounded the cyst, which was very large and attached by adhesions from pedicle to base on the left side. The adhesions were tough and strong. A previous tapping doubtlessly assisted in bringing this about. With as much caution as I could bring to bear the adhesions were broken up, bleeding points caught and ligated

with sterilized silk. At the extreme upper left side of the tumor a large piece of omentum had to be tied off and cut away. The pedicle, which was inserted close up to the uterus on the left side, was ligated in the usual way, Chinese twist being used. After emptying the tumor it was found impossible to deliver the sac without enlarging the abdominal opening, which was accordingly done, the incision extending three inches above the umbilicus. After removing the tumor the cavity was thoroughly irrigated and washed out with hot sterilized water, which, together with the sponges and dressings, was furnished by Mr. Julius Baldauf, of Henderson, Ky. The pulse, which was very feeble, came up wonderfully under the irrigation. The abdominal wound was closed, a glass drainage tube being left in with a provisional suture for closing the opening after removal of the drainage tube.

The subsequent history of the case is given by Dr. P. Ligon, of Rhobards, under whose care Mrs. G. was during my absence. As the treatment after operation in these cases is almost if not quite as important as the operation itself, Dr. Ligon deserves praise for his efficient conduct of it.

"Operation, June 14, 10 A. M.; Mrs. G., ovarian cyst; weight of patient before operation, 136 pounds—twenty days after operation, 90 pounds. Recovered from shock of operation and from anæsthetic well. Tablespoonful of hot water was given every three or four hours; vomited very often. Temperature at 6 P. M., 99° F.

"June 15th.—Temperature 7 A. M., 98.5°; 6 P. M., 98.5°. Vomited several times during the day. At 8 P. M., enema of whisky and milk. Vomited none through the night.

"June 16th.—Temperature 7 A. M., 98.5°; 6 P. M., 100°. Stomach quiet. ℥ij Rochelle salts were given, followed by enema of warm water at 6 P. M. Bowels moved twice during the night.

"June 17th.—Temperature 6 A. M., 98.5°; 6 P. M., 99.75°. No vomiting. Peptonized milk taken every two hours. Drainage tube was removed at 8 A. M. ℥j Rochelle salts given, followed by several actions from bowels during the night.

"June 18th.—Temperature 98.75°, 6 A. M.; 6 P. M., 98.5°. Rested well and feels well.

"June 19th, 20th, and 21st.—Temperature normal. Appetite good. Stitches removed.

"June 22d.—Sat up some and has good appetite.

"June 28th.—Had slight attack of malaria, which was easily controlled by quinine.

"July 10th.—Took the train for Henderson to make a visit."

Saw Mrs. G. on 11th July. Recovery perfect. Those present at the operation were Drs. John Young Brown, Arch Dixon, Jr., of Henderson, Thos. Bethel, P. Ligon, L. Cottingham (who kindly and efficiently gave the anæsthetics), L. Royster, of Cairo, Ky., and Dr. R. H. Moss, of Corydon, Ky. The main object in reporting this case is to call attention to the method of drainage, which was by the usual glass tube (Keith's), perforated near the bottom, placed in Douglas' sac and covered with iodoform gauze. The tube was emptied at short intervals by a piston syringe with a piece of rubber tubing attached. On the first day, two ounces of bloody serum were withdrawn, three ounces on the second, and two and a half on the third. The tube was removed on the fourth day. To my mind Keith's tube is a good one, but it is a trap-door for infection: the door is almost constantly open, and each time the syringe is used your patient is in danger. There can be no doubt that the intestines are the best of all drainage tubes, but there are cases in which the secretions are of such a character that the bowels cannot be relied on to remove them, and then artificial drainage is imperative. Keith's tube is perhaps the best, but could not something be contrived which would do away with the necessity for emptying this tube by the ordinary piston syringe with the rubber-tubing attachment? I have thought that perhaps if the glass tube was filled with strips of sterilized gauze, the strips being the full length of the tube, that the cavity could be kept drained by capillary attraction. If it became necessary to wash out the cavity through the tube, the strips could be removed for that purpose and be replaced again when the injection was finished. Be this as it may, I have known several cases in which secondary infection took place through glass tubes. To surgeons living in large cities, with the advantage of hospitals, well-fitted up operating rooms, and above all, of well trained nurses, this may seem a very ordinary case to report, but situated as country surgeons are, without any of these advantages, we have reason to congratulate ourselves upon the successful termination of operations of much less magnitude than the one mentioned.

The *Columbus Medical Journal* says the weight of experience is that cocaine is more likely to show its toxic properties when injected into the urethra than when used anywhere else.

SOCIETY REPORTS.

HARLEM MEDICAL ASSOCIATION.

Stated Meeting, January 6th, 1892.

Dr. T. H. Manley presented a patient on whom he had operated for hæmorrhoids. Formerly the practice was to give ether and tie or remove these masses, and frequently much loss of blood would ensue with consequent shock. Should the patient be the subject of tuberculosis or syphilis, a chronic ulcer was apt to remain after the operation. A rectal stricture was occasionally noticed after the older methods of operation for hæmorrhoids. Any method which would tend to do away with these dangers must be of advantage. While in Paris, I saw Verneiul operate without general anæsthesia, using cocaine alone. The patient need not tie up and is often able to walk home after the operation. The patient I show you came to the hospital one week ago suffering intense pain from very large internal and external hæmorrhoids. An enema was given and the lower bowel disinfected. The index finger was then inserted in the rectum and a number of injections of a 1 per cent. solution of cocaine were employed, going around the anal margin and along side of the rectal wall. The total amount of the solution used would have made about 100 drops. The sphincter was then stretched with the fingers, and finally, the whole rectum was dilated first with the fingers then by a duck bill speculum. Little or no pain was caused. Since the operation—one week ago—the hæmorrhoids have been reduced to one-fifth the previous size. One great advantage in this way of treating piles is that one physician can perform the operation without any assistance—thus saving the patient expense.

Dr. Van Santvoord: I tried the method of manipulation described in this case and to advantage but used general anæsthesia by ether.

Dr. Gibbs: I also have used this method of dilatation for hæmorrhoids, but employed ether. I can understand the great advantage of employing cocaine and will make use of the suggestion.

Dr. G. H. Cocks: What amount of cocaine would Dr. Manley consider safe to be administered?

Dr. Manley; I have never employed more than I did in the patient before you, viz.: 100 drops of 1 per cent. solution—about 1 grain. I have never seen any evil effects follow the employment of the drug in my hands. One observer has reported 700 cases in which cocaine was used with a maximum dose of 2 grains with no unfavorable results.

Dr. Heiman related a case of a lady who had a fish bone fastened in her throat for one year and three days before removal. At the time it became lodged there, several physicians made the attempt to extract it without success, and as considerable blood was lost, she declined further treatment at the time. There had been no further suppuration, but there was considerable inconvenience in swallowing. When I saw her I employed cocaine freely in the pharynx, and with the mirror was able to detect the end of the bone protruding $\frac{1}{12}$ of an inch above the mucous membrane behind the posterior pillars of the fauces. With a pair of bone forceps I was able to extract it and present it for your inspection. You will observe it is nearly $1\frac{3}{4}$ inches long.

Dr. T. H. Manley read a paper on the Pathology and Treatment of Diseases of the Hip, Knee and Ankle Joints in Children. (See p. 326).

Discussion—Dr. Jas. E. Kelly: I would endorse what Dr. Manley has so ably presented to us to-night. As a supplementary method of treatment of disease of the ankle-joint, I wish to show you an instrument which I invented some 10 years ago and which may yet be new to some of the physicians present. This model of club foot will show the principle involved. The shoe is supplied with a heavy tin sole somewhat saucer-shaped on the bottom and extending two or three inches on the outside from the foot. A band is placed around the calf of the patient's leg and elastic bands are run from this to the margin of the metallic sole. Thus, when the foot is implanted on the floor, the tendency is to assume the normal position, and with the rubber bands any amount of rotation required may be obtained. I have had considerable success while using this instrument.

Dr. E. L. Cocks: In diseases of the joints the diagnosis is seven-eighths of the treatment. The treatment is often very simple if we can only make a correct diagnosis. A short time ago I was called to see a child who had always enjoyed robust health, but was now confined to bed with considerable pain in the left hip-joint. The thigh was flexed on the body, and any motion of the limb gave him much pain. There was no history of tuberculosis in the family and the general appearance of the patient was very good, so I did not suspect tubercular inflammation. Ice was applied to the painful joint, and on the third day extension was employed. The patient

then began to feel better and it was with difficulty that he could be kept quiet. On the twelfth day a modified Taylor's long splint was used and still remains in position. It is a question in my mind when the splint should be removed.

Recently a lady patient of mine sustained an injury to her ankle and there was a doubt whether the external condyle were fractured or only a sprain of the ligament existed. She suffered considerable pain and swelling, but on the third day walked out, as the joint appeared to be better. This indiscretion was followed by intense pain and swelling. She now came to me for treatment and I put up the joint in plaster of Paris and kept it thus for three weeks, and when it was removed I found the parts in a perfectly normal condition.

One argument in favor of operation on diseased joints, where tubercles are suspected, is that a general systemic infection may thereby be prevented. A case came under my observation in a child eight years old who had a tubercular joint, and the patient suddenly developed fever and died of acute tuberculosis. Autopsy revealed cheesy masses in the lungs and other symptoms of a general tubercular infection. It is barely possible that if the joint had been excised the patient might not have developed the systemic infection.

Dr. R. Van Santvoord: The subject of the general pathology of joint diseases presents many interesting features. While a student I listened to the teaching of Sayre, who was opposed to "struma." He depended largely on the traumatic nature of joint diseases. Dr. H. P. Loomis has carefully examined the bronchial glands in a great number of patients who appeared during life to be in no wise affected with tubercular disease. It is remarkable in what a large number he found the bacilli of tuberculosis. We all inhale these bacilli, but they are destroyed before the system becomes affected. Suppose now a local injury to a joint and a certain amount of these bacilli are brought to the part by the blood and the power of resistance being enfeebled at the diseased part, a chronic tubercular joint may ensue. This theory may be in opposition to Dr. Manley's statements concerning the local character of many joint difficulties, but it seems reasonable that my proposition may be true. We know that ulcerative endocarditis is more prone to occur if the valves were previously diseased. Dr. Holt published a case of tubercular meningitis in a child, the determinating cause being a fall on the head. A case came under my observation of a supposed tubercular elbow joint. There were no other symptoms present of a tubercular disease. The patient died after a few days' illness of diphtheria. On autopsy a number of tubercular glands were found undergoing cheesy degeneration.

Dr. J. Gardner Smith: At the Vanderbilt Clinic we are accustomed to employ braces in a large number of the cases of joint diseases coming there for treatment. We always keep before us the suspicion of tuberculosis and syphilis and treat the patient accordingly. Dr. Manley must admit that a leg will become atrophied if the joint is diseased when the patient is put to bed for a length of time, even if braces or splints are not made use of. An advantage in the treatment of these cases with splints is that the limb will remain in a straight condition afterward, while if left to nature, it is sometimes so flexed that locomotion is interfered with. A few months ago a boy 10 years old came under my observation who had suffered from hip-joint disease for three years. There was almost complete anchylosis of the hip. No mechanical means had been employed and the knee was in such a position as to be in the way of a crutch. The foot was up against the opposite calf. The patient was put on the mixed treatment and a long splint applied and gradually pressure and traction were made to bring the limb straight. After treatment for three months he can now place the foot almost down to the floor. If the knee-joint is diseased there is hope of retaining its mobility if the patella remains movable. Rest to the joint when injured or diseased is, very often, all that is required. The application of a plaster of Paris splint frequently cures what appears to be a very serious difficulty. Even in cases of spasms of the muscles this treatment is very beneficial.

DR. A. H. LEARY,
Secretary.

NAPHTHALIN IN WHOOPING-COUGH.

Chavernac (*Lyon Médical*, November 15th, 1891) proposes naphthalin as a remedy for whooping-cough. He places about half an ounce of this substance in a capsule over a stove in the patient's room, which thus becomes filled with the vapors of naphthalin. He states that he has thus obtained a cure in a great number of cases. On the other hand, he has found that patients suffering from early tuberculosis cannot tolerate the vapor; he suggests that naphthalin vapor may thus be an aid in the diagnosis of early tuberculosis.—*Brit. Med. Jour.*

SELECTED FORMULÆ.

DYSENTERY.

Dr. Rossbach (*L'Union Médicale,* No. 9, 1891) speaks highly of the following:

℞ Naphthalin.....grains x.
Aq. bullient.....fl. ʒ iv.
Decoct. Malvæ.....0 i.
Inject by the rectum at a temperature of 100°.

ASTHMA POWDER.

℞ Powd. stramonium leaf.....parts 32.
Powd. belladonna leaf..... " 32.
Powd. nitrate potass..... " 4.
Powd. opium.....part 1.
Burn a little and inhale the vapor.

NEURALGIA AND RHEUMATISM.

℞ Tinct. iodine comp.,
Aquæ ammonia.....āā ʒ iss.
Pulv. camphor..... ʒ ij.
Chloroform..... ʒ ss.
M. Sig. Rubbed in three or four times a day.

—*Dr. Baltzell.*

TETANUS.

Dr. Mayer (*Revista clinica de los Hospitales,* No. 28, 1891) successfully treated a case of tetanus following a gun-shot wound of the thigh with the following formula:

℞ Morph. mur.....cgm. 1.
Chloral hydrat.....gm. 1.
Sod. bromid.....gm. 1.5.
Sufficient for one powder. Three to six powders a day.

Recovery followed after the administration of one gramme (15 grains) of morphine, eighty-one grammes 2½ ʒ) of chloral, and ninety-five grammes (3 ʒ) of sodium bromide.

ALUMINUM IN DIPHTHERIA.

Dr. E. Dickenshied, Spinnerstown, Pa., in a paper read before the Lehigh Valley Medical Association, states that aluminum was first used by his father a decade ago, in a case which he supposed to be hopeless diphtheria, as a disinfectant. The patient recovered, and since then 257 diphtheritic patients have been treated with but two deaths. The remedy is used in solutions as follows:

℞ Aluminum chloride.....dr 8.
Aluminum bromide.....dr. 4.
Boiling water.....dr. 64.
M. Sig. Place over a bath until dissolved.

Its local action on the diphtheritic membrane is to loosen it around the edge and to dissolve it rapidly so as to give the edge a very ragged appearance. Its astringent action reduces throat congestion. The solution is also used, in proportion of one to seven of water, as a gargle or in an atomizer, and at the same time the patient takes from five to ten drops.—*St. Louis Clinique.*

LARYNGEAL DIPHTHERIA.

According to Rosenberry, should be treated with the following:

℞ Ol. eucalypti,
Ol. terebinth.....āā ʒ j.
Ol. vaselini..... ʒ vj.
S. Use in a steam atomizer every half hour.

ULCERS AND GANGRENOUS WOUNDS.

Dr. Brown (*Lo Sperimentale,* No. 16, 1891) uses with success in ulcers and gangrenous wounds the following solution:

℞ Zinc sulphat.....grammes 5.75.
Aq. destillat..... " 600.
Acid sulph. dil..... " 16.

The parts are first washed with warm water and then the antiseptic solution applied on cotton. This dressing is changed every three hours. This causes the fœtid odor to disappear and promotes cicatrization.

ACUTE GASTRITIS.

Dr. Menche (*Lo Sperimentale,* No. 18, 1891) recommends the following in acute gastritis with dyspepsia:

℞ Acid mur. pur., } .....āā grammes 2.
Resorcin sublimat., }
Syrup corticis aurantior..... " 20.
Aq. destillat..... " 178.

RINGWORM.

(SHOEMAKER.)

℞ Cupri oleate..... dram ½.
Adipis benzoati.....ounce 1.
M. Fiat ungent. Sig. Use locally.

ERYSIPELAS.

The following (*La Independencia medica,* No. 42, 1891) has been found of service in erysipelas:

℞ Ichthyol..... .....grammes 15.
Lanolin..... " 15.
Rub upon the erysipelatous surface and cover with salicylic acid gauze.

This prevents the spreading of the disease and calms the pain, in two hours to two or three days.

FORMULA FOR HYPODERMIC INJECTIONS OF QUININE.

Dr. Barillé recently stated to the *Société de Pharmacie* that the addition of antipyrine to the muriate of quinine enables the latter to dissolve easily. He recommends the following formula for hypodermic use:

℞ Muriate of quinine. ....grains 15.
Antipyrine .... " 7½.
Distilled water.....drachm ½.

The solution causes some pain when injected; the addition of ⅓ or ½ grain of cocaine would be beneficial.—*La Médecine Moderne.*

CROUP.

Prof. N. S. Davis says all the indications for treatment, in croup, in the mild or superficial form of the disease, can be fulfilled by the administration of:

℞ Syr. ipecac.....ʒ ix.
Syr. scillæ comp.....ʒ iss.
Tinct. opii camph.....ʒ ij.
M. Sig. Half teaspoonful every three or four hours.

—*Ind. Med. Jour.*

TREATMENT OF INFLUENZA WITH CAMPHOR.

During the recent epidemic, when I had on an average 150 cases a week under my care, I had ample opportunity of testing the efficacy of various methods of treatment. Amongst other drugs, I tried camphor, and with so much success that I rarely prescribed anything else afterwards, six doses or less usually being sufficient. I administered it as follows:

℞ Sp. camph.....dr. ij.
Tinct. lavand co.....dr. ij.
Sp. chlorof.....dr. j.
Mucilag. tragacanth.....oz. ij.
Aq., ad.....oz. vj.
M. Sig. One ounce every four hours.

This costs very little, and by leaving out the flavoring agents the effect is the same and the cost nominal.—*F. W. Devereux Long, in British Med. Jour.*

PURGATIVE PILL.

Prof. Hare gave the following formula, which is very efficient:

℞ Aloïn,
Ext. belladonnæ,
Ext. nucis vomicæ.....āā gr. v.
Ext. physostigmatis.....gr. ij.
Fiant pil. xx.
M. Sig. One at night.

—*Coll. Clin. Rec.*

JAUNDICE.

In a case of jaundice, resulting from catarrh of bile duct or biliary colic, which was sent from here to N. S. Davis, of Chicago, he prescribed:

℞ Hydrarg cor. chlor.....grs. 1-16 per dose.
Potassi chloridi.....grs. ii per dose.
Tr. cinchonæ.....ʒ v.
Tr. hyoscyami.....ʒ iii.
Drachm four times a day.

Recovery soon followed.

DIPHTHERIA AND CROUP.

Dr. Gibert, of Geneva (*Le Progrès médical*, No. 48, 1891), employs the following potion in diphtheria and croup:

℞ Pilocarpine.....gr. ½.
Ammon. carbonat.....grs. xxx.
Potass. chlorat.....grs. xlv.
Syrup polygalæ.....fl. ʒ j.
Cognac.....fl. ʒ v.
Aquæ.....fl. ʒ v.
A spoonful every hour until the patient begins to perspire.

TREATMENT OF SCABIES.

The following is given in *La France Medicale:*

Besnier's Method.—The entire body is rubbed with soap for fifteen to twenty minutes. Immediately afterward a lukewarm soap and water bath is taken. The following ointment is then rubbed in:

℞ Ess. iavandulæ,
Ess. caryophylli,
Ess. cannella.....āā ʒ ss.
Gum. tragacanth.....ʒ j.
Kali carbonat.....ʒ vijss.
Flor. sulfuris.....ʒ ijss.
Glycerini.....ʒ xlv.
M. Et fiat ung.

This ointment should be permitted to remain on the skin for twenty-four hours, during which the patient puts on clean clothes, the others being disinfected in the meantime. Then a bath is taken.

Brocq's Method.—This is a procedure adapted to cases in which the eruption is disseminated and to nursing infants. The following is applied:

℞ Ol. chamomil. camphorat.....ʒ xxv.
Bals. styracis.....ʒ v.
Ess. menthæ.....ʒ j.
M.

Or the following which is less irritating:

℞ Ol. olivar.....ʒ xv.
Ung. styracis.....ʒ vj.
Bals. Peru.....ʒ j.
M.

Quinquaud's Method.—The following is used:

℞ Ung. styracis.....ʒ v.
Vaselini.....ʒ xxv.
M.

Or, a weaker preparation, such as:

℞ Bals. Peru.....grains lxxv.
Vaseline.....ʒ xxu.
M.

In nurslings, he recommends:

℞ Ol. chamomil.....ʒ xxv.
Ung. styracis.....ʒ v.
Ess. menthæ.....grains lxxv.
M.

Ernest Besnier uses the following in pregnant women:

℞ Beta naphthol.....grains lxxv.
Ether sulfuric.....q. s.
Vaselini.....ʒ xxv.
Ess. menthæ.....q. s.
M.

This is to be applied daily, for a week, a starch bath being taken every other day.

NEURALGIA.

We find in the *Memphis Medical Monthly* that Dr. W. M. Hightower recommends the following:

℞ Ammonii bromidi,
Sodii salicylatis.....āā ʒ j.
Tinct. hyoscyami.....ʒ ij.
Aquæ.....ad ʒ iv.
M. Sig. One teaspoonful every half hour until relief is obtained, or four doses have been taken.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO., (Incorporated),
PROPRIETOR AND PUBLISHER.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.,)
Office, S. W. Cor. 36th and WOODLAND AVE.,
Philadelphia, Pa.

CHAS. K. MOUNT, Advertising Manager.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843. Philadelphia, Pa.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by postal note, money order or registered letter.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER; For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Enables the Physician to make out his bills with great ease, and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

BINDERS
FOR THE REPORTER.

Each Binder will hold copies of the Reporter for six months.

"The Medical and Surgical Reporter" stamped in gilt on the back.

PRICE, 50 CENTS.

PLEASE SEND MONEY WITH ORDER.

LEADING ARTICLE.

TUMENOL.

While the list of new remedies that are constantly being brought to the profession's notice is very large, and the number of valuable ones comparatively small, yet, in spite of a gradually increasing feeling of caution on the part of the practitioner in embracing these newer preparations, those which possess any real merit are usually soon recognized. Thus it is that tumenol, a substance obtained from mineral oils, and recently introduced by the dermatologist, Dr. Neisser, appears to have come to stay, and is certainly daily gaining ground among these specialists abroad. The drug is used only as a topical application, and in the form of tincture, solution, oil, salve, or plaster; and, broadly speaking, occupies a position similar to that now held by zinc, with the exception that the claims for tumenol are even greater than those of the former useful substance, at least, in dermatological practice.

The solution has been proven to act more beneficially in cases of acute recurring eczemas of the face and hands, aud also in both acute and chronic eczemas of the extremities. In such cases it is used in a two or five per-cent solution in the form of a wet dressing. It forms a dry protective skin, and greatly allays the itching.

Neisser has also used the solution and tumenol gauze in the treatment of purulent and other discharges from the vagina; but while the remedy was well tolerated, the curative effects obtained were but slight.

Its greatest usefulness is undoubtedly when used as a salve or ointment of the strength of five or ten per cent. It may be made with vaseline or anhydrous lanolin as a base, and of a varying consistency subject to the requirements of the case. Again, the drug may be added to zinc ointment.

Various writers have repeatedly shown how tumenol ointment may be used with greater efficiency in almost every case in which zinc ointment is now used, and its supporters claim that its superiority over the latter preparation is most marked.

Upon ulcerating surfaces in cases of lupus, contagious impetigo, pemphigus, and the periods of desquamation and exfoliation of various other skin diseases, tumenol ointment is claimed to have been used with signal success.

In dry and squamous periods of various skin diseases the tincture gives better results than the salve. The tincture yields excellent results in almost any erosion accompanied by itching.

Tumenol-soap plaster seems to act better and more rapidly than either the plain or salicylated plaster. The oil when applied to the vesicles of eczematous patches acts promptly and beneficially.

Neisser has also used finely powdered tumenol-sulphonic acid as a dusting powder on ulcerating surfaces with excellent results.

In conclusion, the most recent reports of the drug justify our recommending it as a quick drier, a reducer of inflammation, and a healing and soothing application in eczemas, erosions, excoriations, superficial ulcerations, and various forms of pruritus. Its action upon the infiltrations of eczema is but slight, its beneficial influence being confined to the superficial, catarrhal, or desquamative forms of the disease, and especially in the acute forms.

The drug is undoubtedly a valuable one and deserving of serious consideration and trial.

CHROMIC ACID IN SYPHILITIC AFFECTIONS OF THE MOUTH.

For a long time past various largyngologists have recognized in chromic acid a valuable remedy for many diseases of the mouth and pharynx. Its special value is in syphilitic affections of this region, and within a recent date many writers of note have sought to bring the subject before the profession through the medium of medical journals. Among the most recent writings on the subject we have before us those from the pens of Schuster, Vidal, Paget and Feibel.

In placing the results of their experiences before our readers, we merely hope to give them points regarding the most judicious methods for the application of the drug, laying no claim for the introduction of any new therapeutic means, since, without doubt, chromic acid has long been recognized as one of our "stand-byes" in the treatment of syphilitic affections of the mouth.

Schuster has made it a practice first to scarify the syphilitic patches, and then apply a concentrated solution of the acid to the parts. This procedure he repeats once or twice a week until a cure is obtained. His results have been most gratifying.

Vidal, in similar affections uses a caustic solution of the acid (1 to 8, or equal parts of water). This he applies locally for one or two minutes, and then washes the parts with clean water. The treatment is repeated every three or four days until a cure is obtained.

Paget's contribution to the subject consists mainly in a record of the remarkable success which has attended the use of the acid in cases of lingual psoriasis.

Bethin, the London laryngologist, recommends the local application of the acid in cases of chronic superficial glossitis occurring in subjects who have previously had syphilis, and found mostly among habitual drinkers. Another writer, Butlin, recommends the local application of chromic acid three times a day, in the form of a half per cent. solution, as being most valuable in cases of ulcers of the tongue.

Finally, Dr. Ernst Feibel has used the acid in a variety of syphilitic affections of the mouth with such success that he has discarded all other remedies for it. He uses invariably a cauterizing solution of one part of the acid to two parts of water. In cases of syphilitic ulcers of the tongue when a long continued internal treatment had yielded no results, a few applications of the acid produced a complete disappearance of the sores. In these cases the remedy should be applied about every second day, and a week will usually suffice to bring about a cure. In cases of indurated lumps on the tongue a very few applications will effect a cure. The "opaline plagues" also disappeared quickly under its use, as well as ulcers in the angles of the mouth.

In that most troublesome and stubborn form of oral syphilis, described as *lingua geographica*, no other remedy acts in so potent a manner as chromic acid. In such cases the tongue should be first dried, then the solution applied with a camel's-hair brush, and after a few minutes the parts carefully washed. The cauterized tissue will be thrown off in the course of three or four days, and the normal tissue will be found under it. Four or five applications during the course of about two weeks will usually effect a cure. Naturally, cases have been reported in which the remedy did not give entire satisfaction. But in the large majority chromic acid will be found of inestimable value in syphilitic affections of the mouth, bringing about an immediate beneficial action, and leaving as a result a healthy condition of the mucous membrane.

BOOK REVIEWS.

DISEASES OF THE BLADDER AND PROSTATE. By Hal. C. Nyman, M. D., Prof. of Surgery in the Mich. College of Medicine and Surgery; Member American Medical Association, Mich. State Med. Society, Mich. Surgical and Pathological Society, Detroit Academy of Medicine, Surgeon to Detroit Emergency Hospital, etc., etc. The Physician's Leisure Hour Library. Pub. by Geo. S. Davis, Detroit, Michigan.

Another small book having the above title, and one of the series intended to instruct physicians during their "leisure hours," has made its *début*, and will doubtless prove interesting to a certain class of readers who really appreciate the conciseness which is the chief reason for the popularity of this series. The present volume is an exceedingly useful one, and gives a careful resumé of the best and latest knowledge concerning the bladder and prostate, at the same time the author has not failed to insert his personality, and here and there records interesting cases to emphasize a remark. A great deal of technical knowledge is of course included, since it is necessary, seemingly, to satisfy the popular thirst for rules, methods, and explicit indications of all kinds upon the subject of operative procedures. Still, the author has also fairly presented the *principles* which should always be considered more important to the thoughtful surgeon than mere operative technique. In discussing supra-pubic cystotomy, which at the present time is so variously viewed by good surgeons, he takes middle grounds very wisely, and inclines to the more conservative side of the controversy.

As a book of ready-reference, and as a good synopsis of what is known concerning this section of the genito-urinary surgery, we cheerfully recommend it to the profession.

THE PRINCIPLES OF BACTERIOLOGY. A Practical Manual for Students and Physicians. By A. C. Abbott, M. D., First Assistant, Laboratory of Hygiene, University of Pennsylvania, Philadelphia. In one 12mo volume of 263 pages, with 32 illustrations. Cloth, $2.00. Philadelphia: Lea Brothers & Co., 1892.

The author of this new and shorter manual upon the principles and technique of the science of bacteriology has succeeded in getting together in compact and readable form much practical and useful knowledge upon this subject, especially for the beginner. The work is divided into two parts, the first of which tells exactly the materials to be used and the *rationale* of their employment, while the second is devoted chiefly to the description of their practical application in making bacteriological examinations. The illustrations of apparatus, etc., add value to the text, and it is only to be regretted that plates showing some the more commonly met with organisms were not included. We already have, however, in the works of Peyer and Cruikshank, at least two good books for more advanced students, and the present addition to our list must be considered a valuable one, since it presents in concise language most explicit directions for dealing with bacteria in the laboratory. We heartily commend it to students and physicians.

NO. 12. PHYSICIANS' AND STUDENTS' READY-REFERENCE SERIES. SYPHILIS IN ANCIENT PREHISTORIC TIMES. By Dr. F. Buret, Paris, France. Translated by A. H. Ohmann-Dumesnil, M. D., Prof. of Dermatology and Syphylography in St. Louis College of Physcians and Surgeons, etc. F. A. Davis, Publisher, 1891. Price, $1.25.

The present number of this series is the first of three volumes to be issued upon syphilis, and therefore fittingly gives its history as far as Buret has been able to trace it. The mass of evidence which he has most ingeniously put together goes to show that syphilis is a very old disease. The author certainly deserves credit for his labors in this direction, and for presenting to us all the available facts which throw light upon the history of such an important malady. The subject is exhaustively treated, and all proofs of the existence of the disease in prehistoric and early

historical periods of each nation of the earth have been carefully collected and utilized by the author in forming conclusions. To everyone interested in the study of syphilis this little book will be welcome. The translation has not detracted from the value of the work, and, on the contrary, credit is due to Dr. Ohmann-Dumesnil for the very readable book he has produced, and also for his excellent notes with which it is interspersed.

LITERARY NOTES.

—A Journal of Pathology is about to be published in London. The new journal will be under the editorial charge of Dr. Sims Woodhead, who will be assisted by the principal pathologists of Great Britain and Ireland as collaborators and co-editors.

—W. B. Saunders announces the early appearance of several important works: An American Text-Book of Surgery, by Drs. Keen, White, Burnett, Conner, Dennis, Park, Nancrede, Pilcher, Senn, Shepherd, Stimson, Thomson, and Warren; also an American Text-Book of the Theory and Practice of Medicine, edited by Dr. William Pepper, to be completed in two royal octavo volumes. The writers for this work are Drs. J. S. Billing, Francis Delafield, R. H. Fitz, James W. Holland, E. G. Janeway, Henry M. Lyman, William Osler, W. Gilman Thompson, W. H. Welch, James T. Whittaker, James C. Wilson, and Horatio C. Wood. These books will be sold by subscription. Besides, he announces a New Pronouncing Dictionary of Medicine, by John M. Keating, M.D., and a work upon the Diseases of the Eye, by G. E. de Schweinitz, M.D.

WASHING BLANKETS MADE EASY.

If one has a suitable place for the purpose, the washing of blankets may become an easy matter, says the January *Ladies' Home Journal.* In an open space have a line tightly stretched out of doors. To this fasten the upper edge of the blanket. Have strips of cotton sewed to the bottom at intervals; tie these to pegs, which drive well into the ground. Now *turn on the hose.* Cold water, of course, and plenty of it. Drench the blankets well on both sides. If much soiled, rub spots with soap and drench again. The force of the stream will do more than wringing. After the article is quite clean, leave it to dry; never mind if it does rain; if the work has been thorough it will not streak, but be all the better for it. When the sun has completed the task, you will possess blankets as white, soft, and unshrunken as new, and the nap will not be destroyed.

PERISCOPE.

THERAPEUTICS.

COCAINE IN PERITONITIS.

Dr. Julius G. Kiefer states, in the *Kansas City Medical Index,* that the distressing pain and vomiting of peritonitis may be promptly checked by a suppository containing one grain each: extract of opium, cocaine hydrochlorate, and iodoform. It will be safe to use one suppository per rectum four hours apart, if the patient is closely watched for toxic effects, which may be noted by cold extremities and enfeebled heart action. I was led to the employment of the above on the theory of the malignancy of the affection and reversed peristaltic action of the bowel in peritonitis, and the well known anæsthetic properties of cocaine on serous membranes. Alimentation should be temporarily suspended, and enema must be avoided until vomiting is checked.

Any discussion will be thankfully received.

TREATMENT OF YELLOW FEVER BY COLD.

It is well known that yellow fever never develops in a cold or temperate climate, and several attempts have been made at various times to apply this fact to the treatment of the disease in tropical climates by artificially cooling the patient. Thus some thirty-five years ago trials were made with a cold chamber, the air of which was charged with oxygen, but without appreciable success. Quite recently Dr. Garcia has reintroduced a somewhat similar plan, an iced chamber being constructed so that the air within should be maintained at a temperature varying from 32° to 50° F., and nearly saturated with moisture. A fair trial was made with this at the works of the Juragua Iron Company in Cuba, where an epidemic of yellow fever had broken out, seventeen well-marked cases, in all of which black vomit was present, being treated by means of the "polar chamber." Eleven of them recovered, the mortality consequently being at the rate of 35.3 per cent., or about the same as the usual rate of mortality at the mines under other methods of treatment. The course and duration of the disease did not appear to be in any way modified by the low temperature; the urine, though in some cases considerable increased, was not altered qualitatively. The phenomena

depending on acholia occurred in the same manner and at the same period as in cases treated in the ordinary way. The same may be said of the gastric hæmorrhage. The cost of a patient's treatment by cold was found to amount to about $100.—*Lancet.*

ON THE EFFECTUAL AND SPEEDY CURE OF INFLUENZA.

Dr. John Crerar says, in the London *Lancet:* I have formed a new theory of the treatment of acute infective diseases, based on the "analogy of nature," whereby is meant such an inference, for example, that the earth is globular from observation of the uniform shape of other heavenly bodies. Applying this to the study of micro-organisms, I infer that their life and reproductive activity depend upon their inhabiting suitable nutrient media under fit conditions. Thus Klein tells us that a cubic centimeter of beef-tea, kept in an incubator at a temperature of 98° Fr., and peopled by bacilli, multiplies its population 80,000 times in the first twenty-four hours, 450 times in the second twenty-four hours, and only five times in the third twenty-four hours. We thus find that, as the food supply diminished, and the peculiar product of the fermentative process increased, the reproduction gradually declines and ultimately disappears. During the process of reproduction and growth of a micro-organism there is a peculiar substance excreted, or formed, which is baneful to its own microbe, and as this substance increases in quantity it diminishes the vitality of the microbe, and when it reaches a certain proportion it destroys the life of its microbe. When the yeast fungus is placed in an infusion of malt, it grows rapidly, at a suitable temperature, until the alcohol formed in its presence accumulates to twenty per cent. of the whole quantity of the liquid; the alcohol then arrests the growth of the fungus, and the alcoholic fermentation proceeds no further. In the same way, Dr. Burdon-Sanderson has shown that the peculiar secretion of a bacillus is very destructive to the bacillus itself. These facts are of the highest importance when pathogenic fungi are considered in their relation to disease. The application of such facts to the treatment of infective diseases would, then, consist in bringing about in the system a change in the environment of the microbes analogous to that which is spontaneously effected by their own activity, since they apparently excrete products which in sufficient quantity are inimical to their own existence. Hence the possibility of a disease exhausting itself, as it were, without any treatment, provided that the vital powers of the patient can resist the poison more than the microbe that produces it.

It appears, then, that we are continuously liable to attack, but if we can by any means (and I think we can) so alter the state of the body as to make it intolerable to the minute invaders, we secure a valuable truce and gain time to allow the organism to build up a vitality high enough to get beyond the reach of our remorseless foe, and we may thus save our patient. Hitherto the search for such a desirable agent has been chiefly carried on in connection with the cultivation and study of the pathogenic microbe. I propose to look for a similar substance in connection with the changes which invariably take place in the system of the patient during the acute stage of disease—I propose, in fact, to transfer a baneful and death-producing plant—the pathogenic fungus—from its congenial soil and climate in the tropic, to the uncongenial soil and climate of the Poles; and I confidently expect that, in its new situation, it will not long retain its power to do harm. I have practically applied this theory to the treatment of influenza with the happiest results. In the epidemic of 1889–90, I was face to face with an extreme case of this disease, when it was quite clear to me that something more than treatment upon general principles was necessary if I wished to save my patient. A process of reasoning, similar to what I have tried to explain, occurred to me at that time; and acting promptly on the indication to which it pointed, I artificially altered the prevailing state of the patient, with the result that the disease very speedily disappeared. I subsequently repeated my new line of treatment in hundreds of cases, with the same fortunate results. During the present epidemic (1891) I have pursued similar tactics with identical similar consequences. Let me briefly explain what has been occurring. I am called in to see a patient. I find him with a flushed, woe-begone face; intense frontal headache; increased temperature, at the same time perhaps that he is complaining of cold or shivering; a quick pulse, great prostration, and unspeakable distress. I prescribe, and when I visit him next day I find all the acute symptoms gone; no distress, pulse and temperature normal, and the patient comfortable, but weak. On inquiry, he declares, in nineteen cases out of twenty, that the relief was obtained after the second dose of the medicine—that is, within four or six hours after the commencement of the

treatment. Let me instance two cases as typical examples of many others.

Case 1.—Mr. T—— is extremely ill, and believes himself to be dying; pulse 117, with the other acute symptoms mentioned. I venture to assure him that he will be nearly well by to-morrow. Next day I find him quite relieved, and the pulse reduced to 61.

Case 2.—A. F——, a young married woman, who was taken suddenly ill, and when I first saw her she was raving and could not be made conscious of my presence. The next morning she was well, but weak, and I was assured that the second dose of the medicine marked the time of the amendment. On the third day she was quite well, dressed, out of bed, and attending to her duties in the house.

But I have not yet stated the exact nature of my *modus operandi*. Very important results can be obtained through very simple means. In the days of Sir Thomas Watson, the most intelligent answer to questions, "What is the best cure for acute rheumatism?" would be, "Six weeks in blankets, aided by drugs administered on general principles." But the salicylate of soda has changed all that, and has given us a short cut towards getting rid of the excruciating tortures of acute arthritic inflammation of a rheumatic nature; and so with other affections. Having regard to the essential state of a severe attack of influenza, I conceived that I would get the most effective antagonism in greatly increased alkalinity, and the *bicarbonate of potash* was the first agent I thought of. This salt has many advantages. It is not unduly stable to make it difficult to break up in the system. It is also readily eliminated, and thus soon leaves the system; so that the danger of potash poisoning is reduced to infinitesimal proportions. Having found this salt to answer all my purposes, I have not looked for another, although, according to my theory, other remedies of similar nature might easily give like results. I give liberal doses (thirty grains) in a teacupful of milk every two or three hours. I add a few drops of the tincture of capsicum, but this is not at all essential.

A word or two of caution. In two or three cases the action of the heart was weakened to an unpleasant degree; but digitalis and the aromatic spirit of ammonia quickly restored normality. Diarrhœa also sometimes supervenes, but is effectually met by Dover's powder. In cases where weakness is induced by previous disease, or where some other disease was a concomitant, or where pregnancy existed, the action of the remedy was somewhat retarded, but not rendered by any means less certain. Where the salt was intermitted too soon, the symptoms returned; but they readily gave way again on the resumption of the treatment. I trust that those who have the opportunity, will test the accuracy of my statements by careful clinical observations, as I feel confident they will obtain equally favorable results; for the remedy acts uniformaly and satisfactorily: *tuto, cito, et jucunde.*

MEDICINE.

CEREBRAL SYPHILIS.

As a result of his observations during a long experience, Tarnowsky (*Archiv. f. Dermat. und Syphilis*, No. 3, 1891) excludes progressive paralysis and tabes from among the manifestations of syphilis of the nervous system. It is his view that the debilitating influence of syphilis merely prepares the way for the development of progressive paralysis and tabes in those in whom there exists a congenital predisposition to these diseases. Tarnowsky makes the further proposition that if, in cases of syphilis with nervous manifestations, tabes and progressive paralysis can be definitely excluded, 90 per cent. will be cases of cerebral syphilis, in the majority of instances susceptible of cure.—*Monatshefte f. prakt. Dermat. und Syphilis*, July 15, 1891.

THE BACILLUS OF CHOREA.

Berkley (*Johns Hopkins Hospital Reports*, Vol. II, No. 6) reports one case of chorea insaniens in a woman and one of ordinary chorea in a dog in which he has made most careful post-mortem examinations. He concludes his paper with these remarks: "It would seem that chorea might be considered as a general systemic affection, acting with greatest intensity on the vascular system and lepto-meninges, and that its cause is to be sought for in a special bacillus or its toxical product, not a coccus, the staphylococcus aniens being only an accompaniment to the other germ, as in many other infectious diseases. The so-called "choreakörperchen" of Flechsig and Wollenberg are, so far as I am able to judge from the first writer's description, by no means peculiar to chorea; if I mistake not, they are to be found not only in the globus pallidus, but in other parts of the brain, not only in this affection, but also in normal as well as diseased brains.—*Univ. Med. Mag.*

ALCOHOLIC NEURITIS.

Dr. Ernesto Bruschini, of Naples, Italy (*La Reforma Medica*, p. 361, 1891), in a clinical lecture on alcoholic neuritis, recommends: Removal of the cause, hypodermic injections of morphine; antipyretics and analgesics are to be avoided, as they have a debilitating action. Hydrotherapy in general has an excellent influence. Electricity is also of service. In two cases of multiple neuritis the strong faradic current was found efficacious, one pole being held in the patient's hand, and with the other the current was run through the patient's entire body.

PAINS OF CENTRAL ORIGIN.

In discussing whether pain arises from central disease, Dr. Edinger (*Deutsche Zeitschrift für Nervenheilkunde*, Bd. i.) cites the case of a woman, aged 48, who had a slight apoplectic attack three years after the occurrence of endocarditis. The initial symptoms of the stroke were disturbances of sensation in the right limbs and slight transient defect of consciousness. Paralysis of these limbs, with hyperæsthesia and intense pains in the whole of the right half of the body, next developed. Eight months later slight athetosis in the palsied limbs and partial contracture in the arm were superadded. Temporal hemianopsia of the right eye was noted later. The constancy and agonizing character of the pains led to suicide two years after the fit. A small focus of embolic softening was found in the dorsal portion of the external nucleus of the left optic thalamus, extending backward into the pulvinar and slightly involving the internal capsule at the posterior region of Charcot's sensory crossway, the affected fibres apparently belonging to the temporal and occipital radiations. Secondary degeneration of fibres in the mesial portion of inner third of the corresponding crusta was seen. From the level of the posterior corpora quadrigemina downwards the left superior fillet showed fewer fibres than the right. In the medulla, above the piniform decussation, this degeneration affected the whole transverse section of the fillet, being more pronounced in the ventral half. When tracing the relationship between the clinical symptoms and the existing pathological anatomy, Dr. Edinger points out that the absence of degeneration in the pyramidal tracts and of exaggerated knee-jerks in this patient would appear to indicate that the disease of the thalamus has some influence in producing late rigidity. Between athetosis and typical posthemiplegic hemichorea many transitional grades of motor impairment have been noted by various observers. He is disposed to accept Charcot's view that these conditions depend upon destruction of fibres in the hinder part of the thalamus. The rare condition of hemianopsia, from capsular disease, without hemianæsthesia, was probably due to the small extent of the primary lesion. The pains and hyperæsthesia were presumably the consequence of direct contact of sensory fibres with the diseased patch. Descending degeneration of the cortical fillet has several times been observed in connection with disease of the posterior segment of the internal capsule, with or without involvement of the thalamus; hemianæsthesia usually has been associated therewith; very rarely has pain or hyperæsthesia been noted.—*Brit. Med. Jour.*

DOUBLE UNIOCULAR DIPLOPIA.

Thompson, a the recent meeting of the American Ophthalmological Society reported (*Ophth. Rev.*, September, 1891) the case ot a lady, aged 34, who was stunned in a railway accident, and cut in the fronto-temporal region. At first she had homonymous diplopia from pressure on the scar, and paresis of the left external and superior recti muscles. Later she saw double with either eye alone, the images being distinct and separated diagonally upwards and to the right. Tested at various distances and in different ways, her account of the phenomena was consistent. Central vision was $\frac{20}{200}$ and there was great contraction of the visual fields. There were no ocular conditions to account for the impairment of vision or the diplopia. There seemed to be no other evidence of traumatic hysteria, but the opinion was that it was of hysterical nature as most of the recorded cases were. But it was admitted that it was sometimes a symptom of organic cerebral disease, and would then point to a lesion of the occipital lobe.—*Brit. Med. Jour.*

A NEW CLINICAL FORM OF DIABETES.

In an exhaustive paper, Dr. F. Hirschfeld deals with what he considers a new clinical form of diabetes mellitus; and his conclusions may be given briefly. In the majority of patients suffering from diabetes, notwithstanding the considerable amount of food introduced, assimilation continues good; but in a small number the ingestion of albumen and fat is very markedly diminished. This complication remains unaltered in the same patient for a long time. It does not appear that it results from disturbance produced by the

increased amount of food, for most diabetic patients are quite free from it, only a certain proportion being affected by it in a high degree. In no other disease known to us is a similar disturbance of the absorption of albumen and fat observed. The assimilation of fat only is affected in intestinal disorders, and especially in jaundice is much decreased. Whether the diabetic disturbance of assimilation always affects at the same time the two food-stuffs, fat and albumen, is not certain, although it is very probable. Certainly in all cases the lessened ingestion of albumen is evident. The absorption of carbohydrates was always good in the cases observed. The researches of Von Mering and Minkowski on the production of glycosuria, and impaired absorption of food, in the dog after removal of the pancreas, point to the relation of this complication of human diabetes; but it is still not very clear why so many diabetics possess such good assimilation. Clinically, there is a history of frequent and severe attacks of colic, at or prior to the beginning of the disorder, which do not recur later on. One of the most striking of the symptoms is that polyuria is absent, or present in only a slight degree. The urine accordingly appears of relatively dark color, and has frequently a sediment. The fæces are at times pale-colored, but to the naked eye there is no fatty matter apparent. The prognosis is most unfavorable; the explanation of this being that the nutrition of the organism must be carried on under great difficulties.—*Zeitschrift für klin. Medicin*, parts iii. and iv., 1891.

INFLUENZAL INSANITY.

It is rather alarming to be told by so eminent an authority in lunacy matters as Dr. Savage that attacks of influenza have proved to be a potent factor in developing latent weaknesses of the nervous system. The fact that no less than thirty-three cases of this kind came under his observation during, or soon after, the great epidemic, shows that it is a complication numerically of sufficient importance to merit more than a passing notice. There seems to be no disease of the nervous system specially referable to the action of the poison of influenza. All varieties may supervene, from suicidal melancholia to delirious mania, and from neuralgia to homicidal insanity. He narrates one case, indeed, which points to the possibility of influenza possessing a medico-legal interest. A man previously of exemplary conduct developed homicidal propensities during the period of intense mental depression which followed an attack of influenza, and though he fortunately did not kill his youngest child, as he intended to do, the impression left upon his mind amounted to delusional insanity, causing him to give himself into custody as having committed the crime. Had this explanation been broached earlier in the day, numbers of kleptomaniacs and other police small fry might have pleaded post-influenzal neurosis as an excuse for, if not as a justification of, the offences with which they were charged. Dr. Savage considerately vouchsafes a word of comfort in respect of the liability to nervous diseases. He tells us that, so far as he was enabled to make out, influenza was the precipitating and not the prime cause of the morbid process. In nearly all the cases symptoms of disorganization had been manifested prior to the attack of influenza, or the patient came of a highly neurotic stock. The number of people, therefore, who are likely to develop general paralysis or break forth into fits of maniacal excitement after influenza is comparatively small, and for this assurance we must be grateful.—*Med. Press.*

SURGERY.

SOME POINTS IN THE ADVANCEMENT OF THE OCULAR MUSCLES.

The principal points in Dr. Howes' paper read before the *N. Y. State Medical Association* were as follows:—

1. The necessity of always dividing the opposing muscle in cases of advancement. 2. In making the tenotomy, it is not well to attempt to secure the muscle by stitches. Still worse is it to divide the muscle, and then try to find it after it has retracted in the surrounding tissue. The best way is to secure it with a clamp. The clamp forceps formerly proposed by De Wecker are so large that it was necessary to remove them in case the patient was restless or vomited during the operation. A form of a clamp was shown by the writer, which is only about one and one-half inches long, very light but strong. After these forceps once clasp the tendon of the muscle firmly, it can be divided, and the instrument can then be left in place in spite of any struggles or movements of the patient. 3. In the introduction of the stitches, it is best to follow in general the plan proposed by Prince. The writer, however, modifies this by making a sort of "B" shaped loop through the conjunctiva, near the cornea, the perpendicular part being tangent to the edge of the cornea, then through each of the

loops a stitch is passed, from the corresponding corner of the divided tendon. By tightening the stitches, the muscle is advanced to the cornea. If any puckering of the conjunctiva occurs, this is snipped off. In this way, the muscle is not only held accurately in place, but the resulting cicatrix is smooth and produces no deformity. 4. In all cases, an overcorrection should be made, and the degree of that varying with the refractive condition of the eye, according to the well-known tendency to greater divergence in myopia than in emetropia or hypermetropia.

A NEW METHOD OF ESTABLISHING A GASTRIC FISTULA.

Dr. Witzel, of Bonn, describes a recently devised modification of the technique of gastrostomy, which, it is asserted, will prevent the escape of gastric juice, which in many instances causes so much trouble after this operation. The object of this procedure is to establish a canal, formed by stitching together the free borders of two parallel folds of the exposed wall of the stomach. This canal extends obliquely from the right downward and to the left, where it communicates with a small opening made into the interior of the stomach, and an arrangement is thus established which resembles the lower extremity of the ureter as it passes obliquely through the wall of the bladder. It is necessary, in practising this method, to draw a large extent of the anterior wall of the stomach through the external wound. This, it is stated, can be readily effected, when the stomach is collapsed, by gentle and prolonged traction. Two parallel folds following the above-mentioned course are then taken up, the free margins of which are brought together by three or four Lembert sutures, and by numerous ordinary sutures, over a flexible tube of the thickness of a lead-pencil, the lower end of which tube is inserted into the small opening made into the stomach, while the upper end is intended to project from the external wound. The canal thus formed, which should be about one and a half inches in length, is left exposed at the bottom of the wound when the stomach is fixed by sutures to the margins of the external incision. This modification does not necessitate any change in the other steps of the operation, and the surgeon can make the external wound according to his usual practice. Witzel exposes the sheath of the rectus by an incision made parallel to, and at a distance of a finger's-breadth from, the margin of the ribs; then, as is done is House's operation, he separates the fibres of this muscle in a vertical direction, and incises the transversalis obliquely from above downward and from the right to the left. The division of the rectus thus crosses the wounds made through the skin and the transversalis. Witzel, who has operated in the manner described on two patients, has had good reason, he states, for being well satisfied with the results, and believes that his expectation of establishing a gastric fistula capable of being effectually closed by valvular action has been fulfilled —*Centralblatt für Chirurgie.*

TO REMOVE FOREIGN BODIES FROM THE EAR.

Dr. Olivenbaum (*Norsk. Mag. for Lægevidenskaben*, No. 11, 1891) had a young gypsy boy come to him who, while playing with some glass beads, had gotten one into his ear, so that it rested up against the drum-head. He tried syringing, Löwenberg's agglutinative method—a small brush is dipped into glue, introduced into the ear, and allowed to dry on the foreign body—but also to no use. Pulverized alum warmed over the flame of an alcohol lamp was found to furnish an excellent and quickly-stiffening agglutinative substance. He proceeded as follows: Finely pulverized alum is heated in a teaspoon over an alcohol lamp. A wood splinter is dipped into the alum and then quickly introduced into the meatus, held up against the foreign body until it has stuck fast, when the same may be withdrawn. To prevent burning the walls of the ear, a piece of stiff paper may be introduced to line and so to protect them.

THE OPERATIVE TREATMENT OF GOITRE.

Dr. Bally has investigated the material at Socin's clinic, comprising seventy-seven cases of goitre operated upon between 1887 and 1890. He draws the following conclusions relative to the intra-glandular method of operation, which is preferred by Socin:—

1. Intra-glandular enucleation of one or more struma nodules, no matter what be their character, is feasible in most cases. This operative procedure is excluded, however, in malignant struma, and diffuse hypertrophies of the thyroid gland of a parenchymatous or colloid character, as well as in exophthalmic goitre and goitres containing numerous disseminated nodules.

2. In intra-glandular enucleation, it is necessary to find the layer between the cap-

sule of the gland and the strumous nodules, and this can usually be done without difficulty.

3. The hæmorrhage occurring during enucleation, or subsequently from the empty gland, is not, as a rule, dangerous. In the rare instances in which it becomes serious, there is always time enough to change the operative procedure, and to perform a partial extirpation after ligation of the thyroid vessels.

4. Injury to nerve fibres and the consequent paralysis of the vocal cords, can always be avoided by the employment of the intra-glandular method of operation.

5. As regards the chance of recurrence of tumors in those parts of the thyroid which have not been removed, intra-glandular enucleation gives as favorable results as partial extirpation.

6. The operation was never found to be followed by disagreeable consequences, such as tetany or cachexia.—*Centralbl. f. d. gesammte Therapie*, October, 1891.

MODERN RENAL SURGERY.

Dr. A. Obalinski (*Volkmann's Sammlung Klin. Vort.*), says regarding the treatment of severe inflammatory affections of the kidneys and their sequelæ:

Suppurative inflammation of the kidney and surrounding structures indicates the operation of nephrectomy in order that free exit may be given to the purulent and other inflammatory excretions, and that the focus of the disease may be thoroughly cleansed, and further extension to the suppuration to important parts (as, for example, the thoracic and abdominal cavities and the hip-joint) be thus prevented. In most cases the single lumbar incision, as was performed by Simon, will suffice, but when there has been extensive undermining of the peritoneum the formation of a large flap, as practised by Bardenheuer, is to be preferred, as such operation permits of ready access to all extensions of the main pus-containing cavity.

Ureteral fistula should always be treated by removal of the corresponding kidney, provided the surgeon can assure himself of the existence of a sound renal organ on the other side. Nephrectomy in such cases is indicated, not only on subjective grounds and when, for instance, the external flow of urine cannot be restrained by any apparatus and the patient is thus prevented from following his occupation and from enjoying a comfortable existence, but also on objective grounds, since, notwithstanding the utmost precautions, an old ureteral fistula may result in suppurative inflammation of the corresponding kidney and the adjacent soft parts.

Nephrectomy performed under these last-mentioned conditions offers much less favorable prospects than in cases in which there is an absence of suppuration or of cicatricial adhesions.

There can be no doubt that, under equally favorable conditions, the transperitoneal method can be performed more rapidly and with greater ease than the extraperitoneal method of nephrectomy, and that the progress toward recovery is more speedy after the former operation. The transperitoneal method, however, is not applicable to every case, and should be reserved for those instances in which the mischief is confined within the capsule of the kidney, the extraperitoneal method being indicated when the suppurative process has involved the perirenal structures.

OBSTETRICS.

GALEGA AS A GALACTAGOGUE.

Carron de la Carrière (*Revue obstétricale gynécologique*, February and March, 1891,) wishes to call renewed attention to galega as a galactagogue. He found from numerous experiments that the milk of the mother increased in quantity without any diminution of the quality, and that the children increased rapidly in weight. The aqueous extract is preferred, and can be administered in doses of 15 to 30 grains, three or four times a day.

Galega officinalis, galega apolinea and galega tephorsia are the constituents of the galactagogue, nutrolactis.

EXTRA-UTERINE GESTATION WITH PERFORATION OF THE VERMIFORM APPENDIX.

The diagnosis of disease of the vermiform appendix from pelvic inflammation due to disease of the uterine appendages is often a matter of great difficulty. The co-existence of the two conditions is of special interest, and a case reported in the October-November number of the *Bulletin of the Johns Hopkins Hospital*, by Dr. Hunter Robb, resident gynæcologist to the Johns Hopkins Hospital, Baltimore, is perhaps unique. Rupture of a tubal sac took place early in gestation, and a large hæmorrhagic effusion, presumably of slow formation, took place. The autopsy disclosed also perforation of the vermiform appendix,

a condition that had been suspected during life. Most instructive remarks by Dr. William H. Welch are appended, interesting more particularly with reference to the cause of the patient's sudden death.

MANAGEMENT OF ABORTION.

K. Ter-Grigoriantz, of Tiflis (*Centralbl. f. Gynäk.*, October 24th, 1891) has recently treated 60 cases of abortion with great success, owing to the stringent precautions which he adopted. In 8 the temperature was high, ranging from 100.5° to 105.8° F. In one of the 8 the patient had suffered for a week from fever before the author saw her. Septic peritonitis set in and she died two days after the removal of a broken-down fœtid mass from the uterine cavity. In the second there was a history of rough examinations, conducted by a mid-wife. The case recovered after twenty-five days of fever. The remaining 6 recovered after two or three days of the special treatment. Forty-eight out of the 52, where there were no high temperatures, recovered without any kind of complication. In 2 there was rise of temperature for a few days during convalescence; in 1 perimetritic pains set in, without fever, and passed away within a few days; and in 1 hæmorrhage occurred six weeks after abortion. The author's system was to throw up warm douches twice or three times daily and to give ergot in abortion in the course of the first six weeks of pregnancy. Iodoform gauze tampons were employed when hæmorrhage occurred. When the temperature was high, and in all cases of abortion over the sixth week, the membranes and remains of the ovum were carefully removed. This was done with the fingers alone when the os was still wide enough to admit two fingers. The sharp curette was used to scrape the uterus without the aid of the speculum, and after free washing of the vagina, when the os was wide enough to admit that instrument. When the os was small Hegar's dilators, from 7 to 9 millimeters in calibre, were used, and the sharp curette employed after dilatation. Thirty-nine out of the 60 cases were scraped. The process was done very thoroughly, the scraping being commenced at the point on the endometrium where the curette showed that there was most material to scrape away; then the instrument was made to scrape to the right and to the left of that point further and further out until all that was to be removed was taken away. In no case did any evil result follow the use of the curette. A 3 per cent. solution of carbolic acid was found sufficient to wash out the vagina and uterus in normal cases. When suspicious symptoms were present, especially high temperature, the following solution was used for the same purpose: Corrosive sublimate 1 part, carbolic acid 20 parts, boric acid 40 parts salicylic acid 5 parts, chlorate of zinc 10 parts, dissolved in 2,000 parts of water. For injections the author used a Fritsch-Bozemann's uterine catheter with the inner tube not less than 3 millimetres in diameter, else the fluid would not be able to escape freely and quickly, and the danger of carbolic acid poisoning would be considerable.—*Brit. Med. Jour.*

GYNÆCOLOGY.

THE ABUSE OF CATHARTICS IN GYNÆCOLOGICAL TREATMENT.

Loemer (*Centralblatt für Gynäkologie*, 1891, No. 46) calls attention to the fact that the excessive use of laxatives by women leads to paralysis of the muscular coat of the intestine. This condition can be overcome in time by careful regulation of the diet, sufficient exercise in the open air and massage, with the use of both the faradic and galvanic currents. In one case the writer suspended all laxatives and enemata, and persisted with this treatment for eleven (!) days before a movement of the bowels occurred, but after that they moved spontaneously, and the patient's health began to improve.

TWO CASES OF INTRA-UTERINE TAMPONADE.

Oui (*Arch. de Toc. et de Gyn.*, Sept., 1891) reports two cases in which the method recommended by Auvard in his work on Obstetrics, for the checking of hæmorrhage, was adopted with good results. In the first case (one of abortion at four months with retention of the placenta) the flow had already continued for twenty hours, and although it was not excessive the patient was rapidly losing strength. Efforts at dislodging the adherent placenta were futile. Oui, preferring intra-uterine to vagina tamponade, because of the better chances for antisepsis and the greater probability of its exciting uterine contractions, drew down the uterus, and by the help of dressing forceps packed the cavity with iodoform gauze. The tampon was withdrawn the next day, the placenta followed it, and the patient recovered normally.

The second case was one of placenta previa, in which an alarming hæmorrhage resisted all efforts at hæmostasis, such as intra-uterine

douches of hot water, injections of ergotin, and compressions of the aorta. Syncope was imminent. The iodoform gauze was at once introduced into the uterine cavity by the forceps, and packed with the fingers, also filling the vagina. Hypodermic injections of caffeine and ether, the administration of a punch and the acetate of ammonia were resorted to in order to combat the tendency to syncope. The tampon was removed the next day. Symptoms of septicæmia set in twenty-four hours after the removal, but the patient finally made a good recovery. Infection seems to have been due to direct or transmitted contagion from a patient who occupied the next bed to hers, and who died a few days later from septic peritonitis.

DYSMENORRHŒA AND ITS TREATMENT.

E. L. H. McGinnis (*New York Journal of Gynecology and Obstetrics*, January, 1892) says that dysmenorrhœa is the result of one of the following conditions:

1. Chlorotic or highly nervous temperaments (which are often closely associated).
2. An unhealthy uterus.
3. Inflamed ovaries.

Although not regarding electricity as a cure-all, the author states that the treatment, by this agent, of dysmenorrhœa due to inflammatory conditions of the uterus or ovaries, has yielded, in his hand, results far greater than were ever obtained by the use of tincture of iodine, carbolic acid, etc. The method of applying electricity is similar to the practice of Apostoli: After douching the vagina with an antiseptic solution, the intra-uterine electrode is introduced into the cavity of the uterus and passed up to the fundus. The positive cord is attached to this electrode, and the negative cord to the clay pad which is placed on the abdomen over the region of the uterus. The current is turned on very gradually in order to prevent any shock, the strength of the current not exceeding 30 milliamperes, and the seance lasting from three to five minutes. When the dysmenorrhœa arises from ovaritis, the treatment is begun a week before the expected time of menstruation and given daily for about eight minutes. The current is from a faradic battery and is employed as strong as can be borne without much pain. A flat, pliable electrode is placed over the inflamed ovary, and a similar one beneath the lumbar region as the patient lies on her back. After a few applications, the patient will usually be able to tolerate a ball-electrode, connected with the positive pole, placed against the ovary (the negative being on the abdomen), and a current of tension used three times a week. It is scarcely necessary to state that when dysmenorrhœa results from a chlorotic or nervous condition, the treatment by electricity is of secondary importance. The correction of flexions and the wearing of pessaries will also accomplish much for the relief of painful menstruation. Operative interference is required in certain cases—as in stenosis of the canal, polypi, vaginal stenosis or occlusion, imperforate hymen, and certain diseased states of the ovaries. The author asks for a trial of his method of treating ovarian dysmenorrhœa before consigning a patient so afflicted to the operating-table.—*Uni. Med. Mag.*

HELENINE IN LEUCORRHŒA.

Hamonic (*Rev. Obstét. et Gynéc.*, August, 1891) has had excellent results in the treatment of uncomplicated leucorrhœa from the internal administration of helenine. Raw helenine consists of a camphor, an anhydride, and a crystallizable principle — helenine proper. This principle acts powerfully when given internally in cases of acute or chronic gonorrhœa in the male, causing free discharge and increasing the pain without cutting the disease short. On the other hand, it seems to act specially on the glands of the uterine cervix. After a few doses it causes the uterine mucosa to become dry, and the glairy, viscous discharge of catarrhal endometritis disappears under the influence of the drug. Hamonic finds that helenine acts without the aid of any local treatment. It sometimes causes gastric disturbance and diarrhœa, but these complications are exceptional. He finds it best to give raw helenine as a pill, together with inulin, a white amylaceous matter also extracted from elecampane root. Inulin is, however, inert, and confection of roses or any similar vehicle will do as well. The following is the composition of the pill described by Hamonic: ℞ Raw helenine, inulin, aa 15 grains, with sugar of milk q. s., to be made into 100 pills; 2 to 4 to be taken in the twenty-four hours. Helenine is a failure as a local remedy, as it irritates the vaginal mucous membrane.—*Brit. Med. Jour.*

The Toad Poison has been found by Schultz (Nature) to be excreted by special glands in the skin, entirely distinct from the mucous glands, and which are confined to the back of the body, limbs and head. This poison acts as an anæsthetic.

PÆDIATRICS.

RESULTS OF REVACCINATION IN 464 CHILDREN.

Dubousquet and Jasewicz (*Bulletins et Memoirs de la Sociête de Medicine Pratique*, November 1, 1891) give the results of the revaccination of four hundred and sixty-four boys and girls in the public schools of St. Owen. Although one hundred and ninety-one of these had been vaccinated one year before, and most of them with success, yet the revaccination succeeded in 41.87 per cent. of cases. In 1890 an antiseptic wash was used before making the puncture; in 1891 no wash was used. There were no more accidents without it than with it. The highest percentage of success was among the youngest scholars. A large percentage of those who had been successfully vaccinated in 1890 were also successfully vaccinated in 1891. One girl of eight years had been successfully vaccinated in infancy, two years before had had smallpox, and was now revaccinated with success. The conclusions derived are: The necessity of vaccinating children of four to eight years of age, and at frequent intervals thereafter, and of general revaccination in time of epidemics.—*Univ. Med. Mag.*

HYSTERIA IN INFANTS AND CHILDREN UNDER TWO YEARS.

M. Ed. Chaumier, of Tours, read a paper on this subject at a recent meeting of the Académie de Médecine in Paris. He thinks that in very young children hysteria is often overlooked and mistaken for other things. Its symptoms vary according to the severity of the attack. When very slight, it takes the form of frequent causeless attacks of passionate screaming. In more marked cases, the limbs become more or less rigid and the face purple and congested, and sometimes these symptoms are accompanied or followed by tremor. When more severe, the child suddenly begins to cry, and loses consciousness completely: the body is usually stiff and the mouth wide open, but sometimes the body is flaccid. In some cases, these attacks come on in the middle of a fit of coughing, and they are then apt to be mistaken for false croup. He also describes a more aggravated form of the disease, in which the symptoms resemble those met with in adult cases. The child loses consciousness, and becomes quite rigid, with its eyes turned up, and the stiffened limbs may twitch or they may be thrown about wildly. In other cases, the body is quite flaccid and inert. Sometimes such attacks occur at short intervals; they are then often mistaken for meningitis. Hemiæsthesia and hyperæsthesia may exist, but they are almost impossible to make sure of; but contracture and paralysis cannot be overlooked, nor can the absence of the ocular and pharyngeal reflexes, which M. Chaumier has frequently observed. The prognosis is favorable. Recent investigations prove that hysteria is more easily cured in the infant than in the adult; and there is reason to believe that the earlier the treatment is begun, the more likely is it to be successful.—*La Semaine Médicale*, 2d December, 1891.

QUININE AS A REMEDY FOR WHOOPING-COUGH.

Ungar (*Deutsche medicinische Wochenschrift*, April 30, 1891) claims that quinine, although proposed as a remedy for pertussis by Binz in 1868, has not received the attention it merits in the treatment of this disease. From an experience of six years he believes that, after its administration for several days, the severity of the paroxysmal coughing lessens, and the frequency of vomiting and the number of attacks diminish. In some cases the intensity of the paroxysms is unaffected, but their frequency diminishes, and later they become less severe. The disease, however, takes a milder form, and in fourteen days from the commencement of the treatment there is only an occasional attack, or even none. A few cases of failure should not condemn the method, and he attributes unfavorable reports of its success principally to insufficient dosage. He prescribes, three times a day, as many decigrammes as the age counts years, for children up to 4 years of age, and with older children does not exceed a daily dose of 1.2 grammes, except in severe cases in robust children, when he sometimes increases the daily amount to 1.5 grammes for one or two days. To children under 2 years a proportionately larger dose is given, an infant of 3 months receiving 0.05 grammes at a dose, while a 6-months baby may be given 0.1 gramme. These doses are continued for five or six days, seldom as long as eight days. Correspondingly with improvement, the daily doses are decreased from three to two, and finally to one, usually given at night. In case the drug cannot be given in solution or capsule, the bimuriate may be employed hypodermatically.—*Univ. Med. Mag.*

TRANSFORMATION OF VIRUS.

Dr. Chauveau concludes a work on this subject, read at the Paris Academy of Medicine, as follows: 1. Vaccinal virus never gives variola to man. 2. Variola virus never gives vaccinia to the cow or horse. 3. Vaccinia is hence not attenuated variola and cannot be compared to benign anthrax infection communicated to animals by the inoculation of attenuated anthrax virus. 4. If vaccinia is derived from variola, it is by means of a radical transformation of the variola virus, up to the present time beyond the knowledge of experimenters. 5. The attenuation of virus is not an operation that can be identified with transformation.—*Gazette des Hôpitaux.*

BACTERIA IN DRINKING WATER.

Dr. W. Migula (*Centralbl. f. Bakt. und Parasitenk.*, Bb. VIII., No 12, p. 353) makes a contribution to our knowledge of this subject which is really a new departure as regards the examination of drinking water. He points out that, although considerable stress has been laid on the examination of water for pathogenic organisms, there is no reliable rule to guide the hygienist in his examinations for the ordinary saprophytic organisms and their relation to the purity of water to be used for drinking purposes. Dr. Migula washes out small flasks with bichloride of mercury; then, after rinsing them with the water to be examined, he leaves a specimen in the flask, which is plugged with sterilized cotton wadding and covered with an india-rubber cap. It is not necessary to pack the flasks in ice, as it is assumed that if any of the organisms multiply they will all do so, while if the putrefactive organisms (those that liquefy gelatine) grow more rapidly than the others, independent evidence is obtained of the impurity of the water. Cultivations are made in flat glass dishes in order to save the time required in manipulating plates and tubes during the cooling process. After examining 400 springs, wells, and streams, the author has come to the conclusion that where there are more than ten species in any sample of water, especially when these are not species ordinarily met with, the water should not be used for drinking purposes. He found that in only fifty-nine waters was this the case, but that 169 waters contained more than 1000 organisms per cubic centimetre, sixty-six of these having over 10,000 (forty over 50,000). From these figures it will be seen that some of the sources of supply would be condemned by the old method but would be passed by the new, and some condemned by the new would be passed by the old. Migula found in all twenty-eight species, and in a series of tables he brings out the fact that the number of colonies does not by any means correspond with the number of species, though in some cases it undoubtedly does so. This is, in fact, an exceedingly variable quantity. It also comes out that putrefactive bacteria are almost invariable absent from spring water; that they are most frequently found where the number of species is great, and where the number of colonies is between 1000 and 10,000 per cubic centimetre; that they also occur where the number of germs is below fifty per cubic centimetre, but very seldom where the number is over 10,000.

Dr. L. Schmelk, who recently (*Centralbl. f. Bakt. und Parasitenk.*, Bd. IV., No. 7, p. 195) pointed out there is a great increase in the number of bacteria in the water supply of Christiana during the period that the upland snows are melting most actively, now (*Centralbl. f. Bakt. und Parasitenk.*, Bd. VII., No. 4. p. 102) gives further evidence collected during the last three years in proof of his theory. The numbers he finds for those years were ten or fifteen per cubic centrimetre in March to 2500 in April, 1888; 1100 in 1889, and on March 28th, 1890, 5000; the breaking up of the winter snows having occurred this year much earlier than usual. This is the period during which the winter snows are melting, and after this is completed there is no marked increase in the number of bacteria in the lake water until the reappearance of the winter snows, some of the earlier falls of which during October, November, and December melt and disappear. In December the number of bacteria per cubic centimetre sometimes reaches 600, the highest point recorded during the year except in March. Dr. Schmelk thinks that the increase is due to the action of frost in breaking up the earth's surface, from which the contained organisms may be set free as soon as a thaw occurs and then washed away along with the surface soil, just as during great rain-storms. He also points out that the masses of ice projecting into a river may form "collecting" points for the particles suspended in the flowing water, as more bacteria are always found in the water obtained from such ice when melted than in the river water itself. He verified this by repeated experiments. He found, however, that when floating ice was melting in water, though it contained a few more organisms

than water collected near the surface, it held far fewer than water taken from a considerable depth. In the Christiana water-supply he found some thirty species of bacteria, some of which occurred very seldom, some at certain periods of the year only, and a few all the year round. The amount of solids in the water varies from time to time, between 0.92 and 0.94 grammes per litre, and traces of ammonia can usually be found in water during the time that it contains most bacteria.—*British Medical Journal.*

MEDICAL CHEMISTRY.

A NEW METHOD OF ESTIMATING UREA.

K. A. H. Moerner and John Sjögvist have divised a new method of estimating urea which is specially intended for use when accurate results are required.

The most commonly used method at the present time is that by means of hypobromite, and measuring the nitrogen given off, each cubic centimetre of which is reckoned as equivalent to 0.0027 gm. of urea. It is, of course, well known that this method is affected by errors, but the latter are not considered of sufficient importance to render this easy and rapid method unsuited for clinical use. In fact, it is not likely that the hypobromite method will readily be displaced by any other, unless absolute accuracy is required.

The two physiologists above mentioned, however, were in search of an *accurate* method, sufficiently easy and rapid to take the place of the elaborate methods heretofore necessary.

Among these is that of Bunsen, and this has long been regarded as one of the most exact on record. But it also suffers from some sources of error.

The general principle by which the authors operate is to determine the nitrogen of the urea separately from nitrogen derived from other sources. The method of execution is as follows:

Five cubic centimeters of the urine are mixed in a flask with 5 cc. of a saturated solution of barium chloride containing 5 per cent. of barium hydrate. Next, 100 cc. of a mixture of two parts by weight of 97-per-cent. alcohol and 1 part of ether are added, and the whole set aside, well stoppered, until the following day. The insoluble residue is then collected on a filter, and washed with enough of the ether-alcohol. If the filter pump is used, only about 50 cc. of the liquid will be required. Without the pump more liquid will be found necessary and the washing consumes more time. The filtrate is deprived of ether and alcohol by distilling at a temperature which should under no circumstances exceed 60° C. This is best accomplished by connecting the receiver with the filter pump. If no filter pump is available, it is usually preferable to evaporate the ether and alcohol on a water bath, since it is easy here to adjust the temperature below 60° C., while this may be exceeded during ordinary distillation.

When the residue measures above 25 cc., a little water and calcined magnesia are added, and evaporation continued until the vapors no longer show an alkaline reaction (from escaping ammonia). This is usually the case before the liquid has been concentrated to about 10 cc. (The addition of calcined magnesia, above directed, is absolutely necessary if there is any considerable amount of ammonia present.) The concentrated residue is transferred into a flask, water being used to wash the capsule, then mixed with a few drops of sulphuric acid and evaporated on the water bath.

The residue in the flask now contains no other nitrogenized substance besides urea. This is determined by Kjeldahl's method, viz., heating with strong sulphuric acid until the nitrogen compound is entirely decomposed, sulphate of ammonia being formed; this is then decomposed by soda, the ammonia caught in standard acid, and from its quantity the amount of the nitrogen compound calculated.

Accordingly, 20 cc. of pure, concentrated sulphuric acid are added to the contents of the flask, and the latter heated over a naked flame until the liquid has become colorless. Pure soda (free from ammonia, the absence of which in all ingredients must be assured) is now added, and the escaping ammonia caught in a measured quantity of volumetric sulphuric acid. The excess of the latter, left unsaturated, is afterwards titrated back by baryta [standard soda would seem to us preferable, as this will not cause a precipitate], litmus being used as an indicator.

The authors tested the method upon pure urea. By Kjeldahl's method this yielded, as a mean of 5 determinations, 46.801 per cent. of nitrogen, theory required 46.74 per cent. —From *Skand. Arch. f. Physiologie* (by F. Holmgren), 8vo. Leipsig, 1891.

Displacement of the uterus is almost the sole cause of the vomiting of pregnancy.

NEWS AND MISCELLANY.

A PRESCRIPTION.

My pallid friend, is your pulse beating low?
Does the red wine of life too sluggishly flow?
Set it spinning through every tingling vein
By out-door work, till you feel once again
Like giving a cheery school-boy shout;
Get out!

Are you morbid, and, like the owl in the tree,
Do you gloomily hoot at what you can't see?
Perhaps, now, instead of being so wise,
You are only looking through jaundiced eyes;
Perhaps you are bilious, or getting too stout;
Get out!

Out in the air where fresh breezes blow
Away all the cobwebs that sometimes grow
In the brains of those who turn from the light
To all gloomy thoughts instead of the bright
Contend with such foes, and put them to rout;
Get out!

FOR BETTER TREATMENT OF CRIPPLES.

AN APPEAL FOR AN ORTHOPÆDIC DEPARTMENT AT THE PHILADELPHIA HOSPITAL.

At a meeting of the Bureau of Charities and Corrections a communication was received from H. Augustus Wilson, M. D., relative to the establishment of an orthopædic department at the Philadelphia Hospital. In his letter Dr. Wilson says that his attention has been called by medical officers, nurses and medical students connected with and attendants at the clinics of the Philadelphia Hospital, to the absence of that prolonged attention to cripples which modern surgical practice has established as necessary, not alone for the correction, but as well for the prevention of deformity. The short terms of duty of the attending surgeons, he says, and the scattering through the many departments of these cases of cripples is not conducive to their best interests, and necessarily the prevention of deformity is often ignored. The trained nurses that are graduated from this almost perfect training school are deficient in knowledge of matters pertaining to orthopædic surgery, he says, and are obliged to seek elsewhere the opportunity of learning.

The vast number of cases appropriate to such a department, Dr. Wilson continues, are not now systematically used for the instruction of medical students and physicians in the application of surgical, mechanical, gymnastic manipulatives, and therapeutic measures, devoted primarily to the prevention of deformity and correction of deformities already formed. In conclusion, he urged the appointment of one or two orthopædic surgeons to have continuous charge of such an orthopædic department.

The matter was referred to the Medical Board, who were requested to hold a meeting and consider the question of organizing such a department. Should it be determined to organize this department, the Medical Board will advise the Bureau of Charities and Corrections as to the manner of organization.

R. F. Longacre was elected a district physician to succeed Dr. H. B. Martin resigned, and Joseph S. Phifer was appointed messenger at the office of the Bureau of Charities and Corrections.

A NEW coffee adulterant, since the artificial beans have been made quite impossible, consists in roasted coffee beans treated with water for its extractive, which have been roasted a second time after dipping into a sugar solution. The latter re-imparts color and gloss.

THE TEMPERATURE OF DRINKS.

A writer in a German paper gives the following as the proper temperatures for different sorts of beverages: Water, 54°; seltzer water and beer, 57° to 60°; red wine, 62° to 66°; white wine, 60°; champagne, 46° to 50°; coffee, 73° to 79°; beef-tea, 100° to 125°; milk, 60° to 64°; hot milk, 93° to 95°.

ONE of our well-known Philadelphia pharmacists has recently received the following written orders for medicine:—

A dose of castor-oil for a child 15 years old. Be sure and send enough to work her good.

1 Doz. 2 oz. Quinine pills.

1 Bottle Honeatta water.

A. Boo Gee.

1 box of Brandteth's pills, sugar quoted.

Please send enough appecac to throw up a four months old baby.

Two five grain blue mask pills.

10 cents worth partisapated chalk.

To these we will add, from our personal knowledge, the fact of a colored girl always asking for *constipated* lye, when sent for the concentrated article.—*Coll. Clin. Rec.*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most priminent brands of Champagne. I find G. H. Mumm & Co's Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

No Openers required. FOR USE IN SICK ROOMS and families. By a recent and most practicable invention, no openers in future will be required for G. H. Mumm & Co.'s Champagne.
To break the wire—bring the small seal to a horizontal position, and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

The 1884 vintage has been unexcelled in years, and Messrs. G. H. Mumm & Co., secured large quantities of it. Of the 1887 and 1889 vintages, worthy successors to the 1884, Messrs. G. H. Mumm & Co. also bought immense quanties, they making it a rule to lay in sufficient stock of fine vintages to tide over the poorer ones, which accounts for the uniformity and excellence of their justly celebrated Extra Dry, and enables them to supply all demands, while maintaining the same high character of their wine.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830.

CLINICAL LECTURE.

A CASE OF INTERMITTENT CLAUDICATION, OR LIMPING, DUE TO AN ARTERIAL OBLITERATION OF SYPHILITIC ORIGIN.*

By PROFESSOR CHARCOT.
PARIS, FRANCE.

Gentlemen:—I will show you to-day a very characteristic example of an affection which I observed and described in man about 30 years ago.† I have reference to intermittent limping due to arterial obliteration, which can also be called intermittent ischæmic painful paralysis, or still, an intermittent painful paralysis due to an intermittent or functional ischæmia of the extremity. These different names are given by reason of the principal clinical characters manifested. When I speak of intermittent limping, for the sake of brevity, I have reference to the particular variety of the disease which I have described.

I cannot better impress upon your minds this symptom, or rather this especial syndrome, than by making the patient walk before you for an instant. She is a woman 52 years of age, a seamstress by occupation, who recently entered my service.

Sitting, or lying in bed, she does not exhibit any motor disturbances, she can freely move her limbs and feet, but when she is made to walk the characteristic signs appear. Otherwise, there is nothing abnormal. In about two minutes there appears upon the hand a sharp, shooting pain, alighting then upon the calf of the left leg and afterwards upon that of the right one, invading, finally, the instep of both legs. In the mean time the inferior extremities become benumbed, walking is more and more difficult, and the patient at last is forced, by the progressive weakness and the increasing pain, to stop and sit down. Is the train of symptoms completed? Not at all; I have yet to add a new feature which is wanting in the case before us: It is a muscular contraction, a painful cramp which stiffens the extremity attacked and hinders even voluntary movement. Without doubt, this latter phenomenon could be demonstrated in our patient if it were not for the pain that is elicited.

The symptoms developed in the paroxysm soon diminish in severity owing to the influence of rest. The contraction and the pain disappear, and motor-power is re-established. In a short time the patient can resume his walking. Again, however, the phenomena reappear, these coming on after the same lapse of time more or less, about an hour, and hence the justifiability of the term *intermittent limping.*

This patient has been suffering from the disease for the last nine months. At the beginning, 20 minutes or half an hour after walking she would begin to experience the characteristic pain; this became progressively worse until it has reached the present state.

Intermittent claudication is not a disease peculiar to man. Although I have studied it in human beings, it has been observed by veterinary physicians; and I have but to apply to the disease in man the facts furnished by the same malady observed in the lower animals. Bouley in France and Hertwig in Germany have particularly endeavored to demonstrate the existence in the horse of claudication due to arterial obliteration. Here the train of symptoms is always the same, and perhaps these are more marked. The horse trots as if nothing were the matter with him; in about quarter of an hour the animal shows more or less signs of fatigue, his gait being especially weak posteriorly; a stroke of the whip livens the

* A Clinical Lecture delivered at the Hospice de la Salpêtrière, and published in *Le Bulletin Medicale.*

† Charcot — *Comptes-rendus de la Soc. de Biologie,* 1858, et *Leçons sur les maladies du système nerveux,* 1886, t. V *des œuvres complètes.*

beast's pace, but soon afterwards the animal appears to suffer more and more, his hind legs become stiff, and he finally falls. After a little while, the animal recovers, begins anew his work, but before he has gone very far is again attacked by the same symptoms.

The cause of these phenomena is well known: It is the obliteration or the contraction of the arteries supplying the extremity or extremities attacked. In the horse it is the abdominal aorta that is most frequently the seat of the vascular lesion. In the first instance, in which I have been able to obtain a good history, it started in an arterio-venous aneurism of the common iliac; but in man the lesion most frequently starts in an arterial stenosis due to a sclerotic condition of the vessel-walls. Thus, in a case to which I have often referred, in which the appearance of gangrene made amputation of the member affected a necessary procedure, it was found that in the extremity cut off the arteries were in a condition of extreme contraction, scarcely permeable.

I will point out to you in a few words (for further details you can consult my previous works) the pathological phenomena. Collaterally and through the very minute vessels, the extremity involved receives a very limited amount of blood, but sufficient to maintain the vitality of the tissues. Such a quantity of blood, however, is not sufficient to keep up the functions of the corresponding parts, because activity of the muscles implies, so to speak, an excess of work, and therefore, the need of a larger amount of nutritive material.

The same conditions may be produced by experimentation. Placing a temporary ligature at the inferior portion of the abdominal aorta gives rise to anæmia of the lower extremities; the animal exhibits pain; and the muscles deprived of blood become rigid. Taking off the ligature, by which the circulation is re-established, a return of the organs implicated to the normal state is brought about. If the ligature is allowed to remain the lesions will become permanent. This is precisely what happens in the phenomenon of cadaveric rigidity, or in a local mortification which is the prelude of a coming gangrene. Are the results of these experiments instituted by Stenson and Brown-Sequard the same as those occurring in the subject suffering from intermittent limping? Not entirely so. Similar phenomena occur in operated animals, but the symptoms artificially produced by the suppression of the circulation do not disappear spontaneously as they do by simple rest in those cases that come under our observation. We can, however, *mutatis mutandis*, more or less apply to the case of man the phenomena produced by experimental pathology.

We must admit that the arterial lesions producing the symptoms of intermittent claudication, like those seen in an extremity, may, in any other organ, determine at least analogous phenomena. This prevision is realized in many organs in which, according to their function, are produced symptoms similar to intermittent claudication. Thus in affections of the heart, in angina pectoris, the lesions are found in the coronary arteries, at least in the majority of cases. Cerebral vertigo, according to Professor Grasset, is due to arterial sclerosis. Such is the case also in reference to the same organ, in which, according to the excellent studies of Berlin, a lesion of a certain area of the cerebral cortex produces that curious phenomenon known under the name of *dyslexia*. You know what is meant by dyslexia. A person begins to read, everything appears to be all right, but after a certain time it becomes impossible for the reader to continue, and, without knowing what the matter is, is obliged finally to stop. After a little while, the reading is continued, to be followed by the same train of phenomena, and these interruptions go on until, if the reading is persisted in, a true intermittent cerebral halt, as it were, is produced. Pick,* arguing from the evident clinical analogies which exist between dyslexia and the phenomena which we have been studying, and based also upon anatomo-pathological analogies, comes to the probable correct conclusion that there is an identity in the pathogenic process. Considered in its widest sense, this syndrome, intermittent claudication, which by itself forms a most important chapter in pathological physiology, comprises a number of different facts from a clinical point of view, but, nevertheless, recognizes the same mechanism. Thus in a subject suffering from generalized arterial sclerosis, various organs may, simultaneously or successively, exhibit the same train of symptoms, all being the outcome of a common process. I was one day consulted about a case of intermittent limping, perfectly characterized, but, nevertheless, unrecognized up to that time. The condition having been ascribed to rheumatism, electricity was proposed. The beginning of the affection could be traced as far back as three months, and yet these signs,

*Pick—Zur Lehre der Dyslexie.—*Neurologische Centralblatt*, March 1, 1891, No. 5, p. 130.

signs to which we will refer hereafter, announced the coming on of gangrene. Prolonged rest was advised on account of these phenomena, and the limping ceased. In this patient arterial sclerosis was revealed by the sudden blindness of one eye, the cause of which Galezowiski attributed to a thrombosis of the central artery of the retina. It is to another feature of the case which I desire to call your attention. In the patient, suffering from limping of the extremities, there was developed, at a certain period, an analogous affection of the heart, and he finally succumbed to an attack of angina pectoris. Vizzioli has observed, in a diabetic case, a similar succession of phenomena.

After these precursory remarks about the general pathology, let us consider intermittent claudication proper. The syndrome which constitutes the disease is, as I have already told you, a special one. Nevertheless, the same changes or symptoms may be produced, from one point of view, by certain intermittent paralyses of the inferior extremities. Such happened, for instance, in the case of a soldier, 30 years of age, who came to consult me a few days ago. About a year previously he had received a contusion on the foot. After a short time he could, without trouble, undertake to march at an ordinary pace, but if he was obliged to accelerate his walking, he would experience in the course of from 20 minutes to half an hour, a certain weakness of his right inferior extremity and a vague sensation of swelling of the leg, but without a true pain. He would be obliged to stop, rest a little while, and on resuming his march the same train of symptoms would re-appear, and so on indefinitely. We made him walk and examined him very carefully. After from 10 to 15 minutes' exercise, the right inferior extremity, without any sign of real limping, exhibited a peculiar awkwardness; in about from 20 to 30 minutes the trouble attained its height in intensity, and the patient was obliged to take a rest. We explored the right inferior extremity but we found no change of color or temperature; neither did we find any modification in the beating of the pedal or the posterior tibial arteries; the pulse was accelerated, its rate being 112 per minute; finally, there was no pain on pressure over the muscles or over the region of the nerves. During the period of rest the patellar reflexes were markedly exaggerated, especially on the right side; the epileptoid trepidation of the foot could be elicited easily, but only on the right side. These symptoms were somewhat more pronounced after walking. I will add that the patient is free from all cardiac or vascular diseases, and has never suffered from syphilis. He is subject not to an hysteric but to a neurasthenic neuropathy. You have noticed the difference which exists between these phenomena and those which you have already studied. The absence of all circulatory disturbances in the same affected member is sufficient to assure us that, in this case, intermittent limping is not of arterial origin. I dare not say what the true nature of these symptoms is without a more ample information. I am led to believe in a peculiar debility of the nerve-centres, in a rapid exhaustion of them, this being the outcome of continuous activity.

Ischaemic intermittent claudication is due to an endoarteritis which in itself is a permanent and, to a great extent, progressive lesion. In such a condition there is great lack of blood-supply to the muscles when in activity. This being the case, what will be the result if a further diminution in the blood-supply continues? Nutrition, in its turn, will suffer a serious and definite damage; and the disturbances of function will be followed by disturbances of structure. In a word, the danger of sphacelus or gangrene is most imminent. Our patient is on the verge of being attacked by this serious condition. Let us examine her inferior extremities. On the right one the toes and the forefoot, and on the left one the toes alone, exhibit a reddish coloration which is the prelude of gangrene. In both members the arterial throbbing so plainly felt on the level of the femoral artery is absolutely imperceptible in the pedal, posterior and popliteal arteries. If you interrogate the patient she will tell you that she experiences in both feet, at night, shooting pains that interfere with her sleep, a phenomenon which belongs to the initial symptoms of gangrene of the extremities.

Bear this in mind and you will learn that intermittent claudication may take place during the prodromes of gangrene; this is not always the case, but when this symptom appears you must be on your guard, remembering that its appearance leads to a very significant prognosis. These facts are but little known, and they claim a chapter in the classical description of gangrene and its precursory symptoms. Here lies the origin of the mistakes that are frequently made. A patient came to me suffering from gangrene of both feet. After two months he complained of symptoms pertaining to intermittent claudication; in the mean time he had consulted many able physicians. He was told that he was suffering from rheuma-

tism and neuralgia, and was treated with electricity and various topical applications. The disease continued to develop until gangrene set in. It was found necessary to practise amputation, and the operation was performed by my colleague, Terrillon, Surgeon of this Hospice, who has reported the case to the *Société de Chirurgie.*

Are there any chances, by means of a treatment applied in due time, of preventing, in a similar case, the development of such conditions? Yes, most assuredly; we hope to succeed by them, and it is our duty to attempt to do so. It remains for us to decide upon the course of treatment under which we shall place our patient. The affection depends upon, or is caused by, an endoarteritis. But there are endoarterites of various natures; perhaps we may recognize for the disease a special etiology which may, in turn, render it amenable to a particular medication. At all events, it is important not to neglect to make an inquiry into this matter, and I have already examined this side of the problem.

Our patient is not addicted to the alcoholic habit; on the contrary, she is somewhat arthritic. An important fact is that she has arrived at an age when chronic arteritis ceases to be rare. Atheroma, or "the rust of life," as Bichat poetically calls it, may be considered as one of the attributes of senility. "One has the age of the arteries," the well-known aphorism of Cazalis, conveys the same idea. It is true that there are old people wholly exempt from this lesion; thus I have found at an autopsy of a centenarian, performed in this hospital, the total absence of any alteration in the walls of the blood-vessels. This is, however, the exception. According to Bichat, out of ten persons that have passed the age of 60, seven have atheroma. Our patient is not very far from this age. We must, however, examine other hypotheses.

The infectious diseases, notably typhoid fever, do not claim our attention. This cause is wanting in the present case.

In examining a patient suffering from intermittent claudication, we must always think about the possibility of the existence of diabetes. In 1861 I studied one of the complications of this malady, sphacelus, or gangrene, which sometimes associated itself with phlegmons or anthrax of a serious character, attacking, at the very start, the whole of one extremity. This diabetic gangrene of a member is the outcome, in my opinion, of an arteritis, and the cases of Potain, of Benni, similar in nature to mine, support my views. It may be conceived that the same lesion may produce intermittent claudication. I have recorded two cases, and recently Vizioli* has published three more. One of Vizioli's patients died from angina pectoris. According to Ferraro, diabetes may give rise to a special variety of arteritis, characterized by lesions of hyperplastic endoarteritis with tendency to produce marked constriction of the blood-vessels. Our patient, however, has no glycosuria; therefore, we shall no longer dwell upon this point.

Syphilis is one of the causes that ultimately exercise a deleterious influence upon the walls of the blood-vessels. Lancereaux, Virchow, and Clifford Albutt have called attention to its influence in the development of arteritis; but it is Heubner† who has especially studied the true characters of syphilic arteritis. The process begins on the internal membrane (contrary to the opinion of Baumgarten who ascribes the lesion to a gummatous peri-arteritis), followed by the formation of gummatous nodules, etc. We must bear in mind the relative precocity of this variety of arteritis which makes its appearance earlier than the common arterial sclerosis, and the absence of fatty or calcareous degeneration which makes a cure possible.

Do not forget that our patient is suffering from arteritis of the inferior extremities. We have asked ourselves whether arterial syphilis can attack such a seat. As has been recognized by Lancereaux and confirmed by Heubner, it is in the arteries of the brain where the disease finally localizes itself. It has, nevertheless, been observed in other regions, such as the vessels of the intestines (Heubner), in the coronary arteries (Ehrlich), and in the pulmonary artery (Wagner). Prout has pointed out the existence of syphilis in the peripheral arteries, though during his time syphilitic arteritis was not well known. A localized gangrene of the extremities has been observed during a course of syphilis; such is the case reported by Podres. On the whole, we cannot oppose the idea that the malady in question may be determined by syphilis; and it would not be illogical to make such an assertion in the present instance. It all depends upon whether we have sufficient reasons to believe in the presence of the infectious taint in this case. We have, I think, very

* Vizioli:—La Claudicazioni intermittente come mezzo diagnostico nei casi di diabete decipiens. *Commun. a l'Academ. med. chir. de Naples*, Naples, 1891.

†Heubner:—Die luetische Erkrankung der Hirnarterien, Leipzig, 1874.

clear and convincing reasons, and these are furnished us by sufficiently characteristic evidences.

The patient suffered at about the age of 15 from articular pains which lasted for 18 months. Of late she has been subjected to attacks of migraine, accompanied with vomiting. These phenomena pertain to arthritism and point to the presence of syphilis.

In 1860, at the age of 24, there appeared upon the dorsal face of the feet a painful tumefaction which disappeared after a certain time, leaving as a vestige a small exostosis which still exists. Did she have, then, osseous gummata? Such is possible, but what follows is still more typical. Ten years later, at the age of 34, she suffered from a tenacious coryza, a rebellious sore throat, necrosis with the expulsion of the nasal bones; and thus you see her nose is deformed and flat. There is a small perforation of the soft palate, with irregular borders, a lesion which probably dates from that time. Five years elapsed.

In 1875 gummata developed in the region of the shoulder; a focus larger than the rest empties into a fistulous canal which gives passage to mortified fragments of tissue. Small cicatrices seen around the region are the present vestiges left by the application of the cautery as a therapeutic measure. The shoulder articulation is perfectly healthy. This is not all. From November, 1890, to January, 1891, that is, during a period of 3 whole months, the patient suffered day and night with an intense cephalalgia and consequent insomnia. She was given iodide of potassium during the last six weeks of this period, and the pains gradually decreased. In January, 1891, the first symptoms of rachitis made their appearance; these afterwards diminished, but did not disappear entirely. There was found at the superior portion of the dorsal region of the vertebral column an abnormal, hard protuberance, formed by a transverse and antero-posterior thickening of the spinal ridge. It was probably a developed syphilitic Pott's disease. At the same time symptoms of partial epilepsy were noticed, the aura beginning at the left superior extremity, extending to the leg of the same side, accompanied with sensations of vertigo, followed by transitory paralyses of the affected members. The various symptoms which I have described were, on the whole, combated by iodide of potassium and mercury. Their syphilitic nature did not escape the notice of the attending physicians. Immediately after the cephalalgia, intermittent claudication appeared for the first time.

I will summarise. Here is a history of a serious tertiary syphilis which has given rise to the development of the present conditions. We have no reason to deny the power of syphilis to produce in the extremities a specific arteritis. The part played by syphilis in the present case is sufficiently clear, and thus we must direct our treatment accordingly. What risks would we be apt to run, after all? If our hypothesis is false, no harm will follow; if it is exact, the chances are that our interference will be productive of the best results. To conclude, then:

1st. We must order, as is our duty to do in all cases of intermittent claudication of arterial origin, a prolonged rest. Strictly speaking, it is not absolutely necessary to require patients to rest wholly in bed; it is only essential that we prevent in some way the appearance of the symptoms of the disease in question. This means, patiently employed, may bring about the complete cessation of such symptoms.

2d. To diminish the pains which are particularly torturing at night we must have recourse to the use of opium. Rest will suffice sometimes to allay them.

3d. Finally, we must push the iodide of potassium, administering it in large doses, and employ at the same time mercurial frictions.

Can we succeed in checking the progress of the disease, and make it recede at the same time? It is hoped that such will take place, At all events, we shall have our conscience clear by having tried to prevent the progress of the disease, and of having combated the abnormal conditions by means of rational therapeutics.

PLASTER OF PARIS FORMULA.

1. *To Make Plaster Set Hard.*—Mix best plaster of Paris with about 10 per cent. (more or less, according to effect ascertained by preliminary experiment) of very finely powdered marble (calcium carbonate). Or add to it about 6 per cent. of powdered alum, or about the same amount of ammonium chloride, before mixing with water.

2. *To Make Plaster Set Slower.*—Mix it with 2 to 4 per cent. of powdered althæa root before adding the water. This not only retards the hardening of the plaster, but also enables it to be cut, filed, sawed and turned.

An addition of 8 per cent. of althæa powder retards the complete setting of the plaster for about one hour, so that the mass can be used for any purpose where it is to remain plastic during at least a portion of that time.—*Amer. Drug.*

COMMUNICATIONS.

REMARKABLE COLLECTION OF FOREIGN BODIES IN THE STOMACH.*

By JOSEPH D. CRAIG, A. M., M. D.
LECTURER ON AND DEMONSTRATOR OF ANATOMY IN THE ALBANY MEDICAL COLLEGE.

The following abstract of a case in which a remarkable collection of foreign bodies was found, *post mortem*, in the stomach, is worthy of record, both on account of the unusual number and character of the substances obtained.

The history of the case is as follows: Emma F., aged 24, was admitted to a hospital for the insane, Nov. 24, 1890. She was a servant by occupation, a native of Sweden, had been in the United States three years and was unmarried. Up to the time of her commitment the records state that both her parents were dead, and that she first became insane in March, 1889, that she was non-pregnant, and that the supposed cause of her insanity was delayed menstruation. After ten months' continuous custody in a County House, she was discharged in April, 1890, and was afterwards employed as a domestic for seven months. During these seven months the patient showed evidences of returning insanity, and she was finally taken to a State Hospital in November, 1890.

"On admission," says the hospital record, "patient took but little interest in her surroundings, was confused, childlike and incapable of giving a reliable account of herself; in fact, during her entire residence in the hospital, it was almost impossible to engage her in conversation, and when she was disposed to talk, she used such broken English and was so incoherent as to make it extremely difficult to follow her. Her general health was apparently fair, and she weighed 150 pounds. In the latter part of December, she began to fail and complained somewhat of colicky pains in her abdomen and had some diarrhœa and vomiting. Under treatment these symptoms subsided and she was able to occupy herself with light work about the ward until March, 1891, (about two months before she died) when she again complained of pain in the stomach, and vomited. About this time she had three profuse hæmorrhages from the bowels, which were very dark in color and attended with considerable griping. A careful examination of the abdomen was made and no evidence of a malignant growth was found. Several examinations of the chest had been made previously and there had been discovered some evidences of consolidation of the apices of the lungs. At this time another examination was made and the consolidation on the right side had increased. From now on she failed rapidly, became much emaciated, had night sweats, and coughed and expectorated a great deal. She did not, however, have any further stomach or intestinal disturbance until the 20th of April, when she again complained of pain. She had frequent attacks of vomiting, but did not eject anything resembling blood.

On May 23, she had two hæmorrhages from the lungs, and also some bleeding from the nose. She took nourishment fairly well and appeared to be free from any distress.

On the 25th of the same month, she was again troubled with vomiting, but had no pain with it. It was necessary to catheterize her for retention of urine. The vomiting subsided in the course of 24 hours and she had no further attack.

She died on the 29th of May, having successfully concealed from her attendants the fact that she had swallowed any foreign substance. The cause of the hæmorrhages and of the bloody stools and of the vomiting in March, two months previous to her death, was also unascertained during her life.

The body of this woman being unclaimed was duly received at the Albany Medical College early in June, was embalmed and preserved for dissection. On November 30, dissection was begun and about two weeks later the following articles, 120 in number, were found collected together partly at the pyloric end of the stomach and partly in the ascending portion of the duodenum.

1. Fifty-one pins.
2. Sixteen needles, (whole or part).
3. Three darning needles.
4. Thirty-two nails varying in length from a half inch to three inches.
5. Two screws, one of them $2\frac{1}{2}$ inches long.
6. Three pieces of iron, $3\frac{1}{2} \times \frac{1}{4}$ inch.
7. Two rolls of hair.
8. Two pieces of wood.
9. Three pieces of cloth, each 5×1 inch.
10. Six hair pins.

The metal pieces were very much corroded and some of the pins and hair pins were bent. The rolls of hair and pieces of cloth were not preserved on account of their very offensive odor and from the fact that they presented nothing of unusual interest.

* Read before the Medical Society of the County of Albany, February 10, 1892.

The pieces of cloth were evidently torn from the calico dress and underclothing of the patient. It is to be regretted that, owing to the advanced state of decomposition of the body, other portions of it, particularly the lungs, could not be satisfactorily examined.

Patients are occasionally found among the insane and hysterical who swallow various foreign substances, but it is unusual for them to introduce into their bodies so great a variety and so large a number of articles as were found in this case. There seems also to be a desire on the part of such people to conceal, not only the fact, but also the manner of the introduction of extraneous bodies, and even when the evidence is conclusive of the actual presence of needles or pins in the tissues, they will deny any knowledge of the way in which they were introduced. This concealment is not due to any sense of regret or chagrin or shame but from an obstinate insane determination, and seems to give them satisfaction and pleasure to prevent the attendants from obtaining positive information. It is also quite clear that these substances are not used with suicidal intent, but that, with the loss or perversion of the reasoning powers, there is an inability to properly estimate the consequences of such an act. These cases also occur most frequently among women, and among women whose insanity is due to some perversion of the menstrual function.

In order that this case may present greater interest, I have grouped with it three others which are noteworthy from the large number of substances found. The brief histories of these cases are as follows:

The first case is taken from the records of one of the State hospitals for the insane. This patient was also a woman from whose neck and abdomen were removed eleven hair pins, nineteen pins and one needle. Nothing could be ascertained in regard to the manner in which these substances were introduced into her body as she could not be induced to make any statement regarding them.

The second case was reported by Dr. Judson B. Andrews in the *American Journal of Insanity* for July, 1872. A very brief abstract is here presented. This patient was also a woman, 30 years of age, a seamstress, single, with no hereditary tendency to insanity, was of a highly nervous and excitable organization, emotional and irregular in feeling. She suffered at various periods from severe pains in the head, and with delirium at menstrual periods. Had also at various times attacks of acute rheumatism, and diphtheria, and, finally, peritonitis, from all of which she recovered. To quiet the pain and distress of these diseases she took morphine hypodermically, becoming at last addicted to the drug and using about a dram and a half per week.

Just before her admittance to the asylum, she purchased ten papers of needles, only two of which could be accounted for except as they were removed from various parts of the body. When first brought to the asylum, she was maniacal. These maniacal symptoms gradually subsided and menstruation, suppressed for two years, began again with scanty flow, much pain, and delirium. Three months after her admittance a broken needle was extracted from her right breast, which was inflamed and extremely sensitive. From this time to her death after seven months' confinement in the asylum needles were removed from her left breast, the abdominal parietes, the mons veneris, labia and vagina. Some were removed from the thighs and legs down to the ankle, from the buttocks, from about the arms and from the back as high as the shoulders. As many as twelve needles were extracted in a single day. This woman, like the other two, repeatedly and persistently denied any knowledge of having introduced them either by the stomach or skin. A strict watch was kept of the patient at all times. She must have introduced the needles before reaching the asylum, and as they were all of them rusted, must have been in the body for some time. Their presence produced little local irritation and did not produce a fatal result.

Two hundred and eighty-six needles were taken from the body during life, three were passed from the rectum during sickness, and eleven were taken from the tissues after death. Of the number, 300 in all, 246 were whole and 54 parts of needles. Of the 300, 170 were found in the breasts, 60 in the abdominal wall, 20 in the genitals, 30 in the thighs and legs, and 20 in the back.

The third case was reported by Dr. Bastian, of London, at a meeting of the Clinical Society of London, held on December 14, 1891. The brief history is as follows: Eighty-six needles and one pin were removed from a body of a woman, an inmate at that time of the work-house at Guisborough, England. Fourteen needles were still to be felt in different parts of the body, and some the needles extracted were from $3\frac{1}{2}$ to $3\frac{3}{4}$ inches in length. The patient was fifty-five years of age, and had suffered from epilepsy from childhood. This woman was fairly intelligent, had occasional fits of bad temper, at which times she refused food. She

had no morbid appetites, was accustomed to much sewing, and often had packages of needles in her possession. The needles had all been extracted by the doctor, the nurse, or the matron, or by the patient in the presence of one of the three. They had also, with one exception, been extracted from the hypochondriac, lumbar and iliac regions, or from the buttock or thigh of the left side, on which side there was some blunting of sensibility. Like the other cases, this patient would not make any definite statement as to how the needles were introduced, neither did their presence give rise to anything more than irritation and tenderness when they were approaching the skin and were about to emerge.

To sum up these four cases, in conclusion, it is found that they present the following characteristics in common:

1. The large number of bodies found.
2. Their presence in each case in a woman.
3. The persistent refusal of each to give any information as to what manner the bodies were introduced or that they were introduced at all.
4. The length of time these foreign substances, particularly the needles, remained in the body without giving rise to dangerous complications.

SOME CONTRA-INDICATIONS FOR THE USE OF OPIATES.*

By MARIE B. WERNER, M.D.,
PHILADELPHIA.

My object in presenting this subject before the Society to-night is that I wish to show that in general practice the indications are limited for the use of opiates. We must fully realize that we have a broader basis for medical science than symptomatology, in order to give our patient the full benefit of our knowledge. Our position being at all times one of trust, we must endeavor, in helping our patient, to find the cause and remove it, rather than hide the symptoms it gives rise to by an opiate. Aside from the possible mental disturbances such a course of treatment might induce, it often materially complicates surgical efforts to relieve patients, the results of which we have repeatedly heard discussed at these meetings.

In order to discuss this drug with due fairness, it will be necessary to give a few moments to the consideration of its pysiological action on the human economy. Dr. H. C. Wood, in his *Treatise on Therapeutics*, says: "When opium is taken in such a dose as to produce its mildest physiological effects, it exerts a quieting influence, inducing a peculiar dreamy condition; after a length of time, varying according to the idiosyncrasies of the patient and the dose of the drug, this condition passes into sleep, either light, dreamful, natural, or heavy, and deepening into stupor. On awakening, the patient may return at once to his normal condition; but very often he experience a state of depression, shown by languor, a little headache, nausea, or even vomiting, which may last for some hour. One of the most common of these departures from the ordinary course of symptoms is an excessive depression following the sleep produced by moderate doses of the medicine. This state is seen, as far as my experience goes, most usually in females of weak, nervous organization such as are peculiarly liable to attacks of neuralgia. The symptoms are a feeling of weakness and prostration, often accompanied by chilliness, a dull headache, and giddiness, but especially marked by nausea and frequent vomiting."

Bartholow states that, as a rule, opium does harm in all gastro-intestinal maladies in which there is a deficiency in the proper secretion, or a suspension of the functions of the liver and kidneys.

Dr. J. B. Mattison, in his valuable paper before this Society in October, 1890, entitled "The Renal Status of Opium Habitués," after a careful analysis, arrived at the following conclusions: First, the habitual use of opium in any form will cause organic renal disease; second, the changes most likely to be met with are cirrhotic; third, that the rationale is threefold—vasomotor changes, impaired general nutrition, and inflammatory action due to non-eliminated irritant products. I would further call attention to the valuable contributions of Dr. A. Haig, published in the *British Medical Journal*, 1890, in his studies on the influence of opium and morphine on uric acid; also, of the retention of this latter product in the human economy, and its relation to the causes of disease. His observations and experiments proved to him that the administration of opium or morphine caused retention of uric acid, accompanied by a reduction of arterial tension; that, when the effect passes off, there is a rebound, with an excessive excretion of uric acid and marked high tension, often accompanied by headache and mental depression.

* Read before the Philadelphia County Medical Society, January 27th, 1892.

Let us look carefully into these statements and compare them with our practical experience; we find that, after lulling pain and induction of sleep, we come to a period of depression, even after a moderate dose of the drug. The depression is usually followed by a certain loss of resistance to bear any renewal of pain, and, in consequence, it becomes necessary to repeat the use of the drug; indeed, when we study carefully its action on a previously weak, nervous organization, we find the description given by Dr. Wood very ably describes the case for us. He tells us: "The symptoms are a feeling of weakness, prostration, chilliness, dull headache, nauseau, etc." In the face of this the questions must certainly present themselves to us: Is it wise to simply gratify the desire of the patient? Would it not be better to study the cause and remove it rather than hide the symptoms which lead us to the origin of the trouble? I refer to cases in everyday practice; cases in which a periodical monthly pain is lulled to sleep by several doses of morphine or opium, while the proper cause is entirely left out of sight. There is no doubt in my mind that cases have come to all of us where a case of chronic constipation or continuous indigestion, combined with a nervous, irritable temperament, perhaps, added to that, or independent of this, an unpleasant skin eruption, etc., claimed our attention.

Quite often a question regarding any menstrual difficulties shows that there is some pain, often varying in severity, and the next question, What do you do for the pain? will elicit the answer: Oh! I take a little paregoric, or I have some pills or suppositories I use, perhaps previously given to some member of the family for pain. Not infrequently an investigation will show that the main ingredient is an opiate.

In our day of progressive medical science it becomes necessary that we should join hands and forces—first, to see if the proper hygienic rules regarding clothing, exercise, and cleanliness are scrupulously carried out, and that the proper functions of secretions and excretions are thoroughly understood. If aside from these precautions there is still pain, a local investigation should be made by the physician, and the condition carefully studied, the cause removed if possible. To give an opiate in such cases I consider criminal, since the patient receives a double injury; not only is she not relieved permanently, but she is robbed of much of her normal resistance, and I fear many have become chronic invalids, for it is a constant struggle to overcome the after-effects of the opiate before the time arrives for another relief of the same sort. If the patient escapes becoming addicted to the opium habit, she cannot escape the local gastro-intestinal irritation which is invariably set up, and which will defy all medication so long as its cause is kept up.

I can at this moment call to mind three cases, in which three weeks out of four all sorts of laxatives are used to overcome the amount of morphine taken during the fourth week; the complexion is sallow, the breath heavy, the skin impure, and how can it be otherwise? If an examination reveals no functional trouble other than the local congestion, or possibly some displacement downward induced by improper clothing or a lack of attention to the proper excretions, is it not at once clear that an opiate in the long run increases the cause of pain? Lulling the pain induces no cure, and the resulting constipation acts in two ways to make the patient worse: first, the pressure of a distended bowel; second, the absorption of effete products. Let such conditions continue for some years, as they often do, and we have other factors enter the field to make life miserable—a sluggishly acting liver or kidneys, a worn-out stomach, and not infrequently a nervous wreck.

In order to emphasize this point, I will only have to call attention to a series of comparative experiments on animals* made by Dr. Edward Levinstein, and reported in his book on *Morbid Craving for Morphine*, whose deductions from a number of experiments are as follows:

"1. That internal applications of morphine sooner paralyze the digestive powers of the stomach than the subcutaneous injection.

"2. Both ways of administering morphine bring on functional disorders of the secreting nerves.

"3. Both cause catarrh of the stomach and intestinal tract.

"4. Large doses of morphine given internally cause a subacute catarrh of the stomach, on account of the irritating chemical action of the morphine.

"5. The subcutaneous injection of morphine causes a chronic catarrh of the intestines in a mechanical manner, in consequence of the impaired influence of the secreting glands, due to the action of the morphine; the secretion of the digestive

*Covering a space of time from six days to five weeks.

fluids is stopped altogether, or at least diminished in quantity, and consequently the intestinal tract is encumbered for a longer time by the ingesta."

The same author speaks of amenorrhœa and sterility as being a sequence of the continued use of morphine, drawing largely upon the results of his own observations, and accepts Pflueger's theory in explanation of it.

In these days, when "preventive medicine" is being advocated by all of us who desire to place medical science on the highest standard, should we not think many times more than twice before we write a prescription for an opiate to relieve pain? In the face of all these facts, it becomes a serious question of right and wrong if we stop short of exerting all our knowledge to study the *cause* of the pain we have been called in to alleviate. Often the prescription-book is entirely useless, unless its blanks could be filled with directions to the patient how to dress, eat, and give herself the physical care she needs.

The use of morphine after pelvic operations has been discarded by most of our operators, and clearly has been the means of reducing mortality rates as well as obviating many of the dreaded after-complications. I recall in one of my earlier operations the advice given by one of our older physicians to rely on opium and calomel, which I followed, with the result of having on my hands a sufferer from insomnia and chronic constipation after I had discontinued its use; had I not been careful to destroy all prescriptions, I feel certain I would have had more trouble. Another case comes to my mind of a patient who had a section done for some pelvic trouble by a physician, who also believed in the opium after-treatment. This patient came under my care later, and confessed that she had often helped herself to a suppository after the doctor had stopped their use. My object in referring to these cases is to show the danger of setting up the morbid craving and its attendant evils with only medicinal doses and in the space of two or three weeks; showing at once the danger a prescription containing an opiate may induce in the hands of a nervous patient who has periodical attacks of pain. Such cases do not alway reach the state necessary to require hospital treatment; hence are often exceedingly vexing to the physician and surrounding friends. A direct accusation to the patient would often fail to bring the results desired, while the friends and relatives cannot always be relied upon for the tact and discretion so necessary. For that reason the physician must often exercise a vast amount of patience and time to educate the ones immediately concerned, and to prove the deleterious effects the use of opiates have, and then, *perhaps*, the patient can be cured.

It may, perhaps, be of interest to quote from a discussion on morphine in the British Gynæcological Society, 1889: Dr. Bantock gave us his experience after surgical operation "that patients were much better off without it—they escaped the restlessness which was left as the opium wore off." Dr. Bedford Fenwick called attention to the fact that opium increased the congestion of the kidneys to a dangerous extent, and might even go to a complete suppression of urine; also, that it caused a complete atony or paralysis of the muscular tissue of the intestines, thus preventing their acting. Dr. R. T. Smith had given two doses of a quarter-grain of morphine each in a case of severe shingles; the patient had suppression of urine for twenty-four hours. Dr. Thomas Savage, in his address read at the annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association, says: "It is not long since it was the custom to administer opium and morphine as a routine treatment in all cases of peritonitis and many other conditions in the abdomen. We have now learned the inadvisability of so doing. May we not extend the withholding of these and similar drugs in other states? I have myself thought that the general practitioners rely too much upon anodynes."

In this matter of too sympathetic and assiduous medical treatment errors rather of judgment than intention are often committed.

Of no less importance is the behavior of an opiate on a patient of uric acid diathesis, in which a demand for relief of pain on the part of the patient often becomes quite urgent. Here again the researches of Dr. A. Haig show us that the drug tends to store up the acid; that when elimination begins to take place there is often a return of the pain, the patient again demanding relief—in this manner a cycle can easily become established. These pictures teach us the impotance of keeping the drug *entirely out of the reach of the patient*, and the necessity of its *careful* and *conscientious* use where it may be indicated.

DIAPHRAGMATIC HERNIA.

By JOHN M. CURRIER, M. D.,
NEWPORT, VERMONT.

On January 14th, 1892, I was invited to be present at an autopsy of a man who had died the day before. He was sixty-seven years of age; body well nourished. On January sixth the patient ate some pea soup for dinner; shortly afterwards he was taken with pains in his bowels, which was treated with domestic remedies, only partially getting relief. Vomiting came on, colic increased, and a physician was called who relieved him by the use of hypodermic injections of morphia, but the symptoms soon returned. It was necessary to keep the patient under the influence of anodynes in large doses, to give him any comfort. He had only one evacuation from his bowels after he was taken, although repeated injections had been given. Very dark grumous matter was ejected from the stomach. The patient continued to grow worse until his death early on the 13th.

The autopsy was held thirty-two hours after death. An incision was made from the top of the sternum to the os pubis, through the skin and subcutaneous tissues to the sternum, and through the abdominal walls. On turning these abdominal flaps to the right and left the ascending colon was brought into view; it was distended with gas fully four inches in diameter; the head of the colon was displaced, and laid up in the hernial sac through an opening in the diaphragm extending from the mediastinum to the right five inches along the thoracic walls. The head of the colon was pendulous fully twelve inches, and seemed to have floated around in the abdominal cavity at all times according to the amount of gas it contained. The head of the colon which laid in the sac was highly congested. The appendix was seven inches in length and one-fourth inch in diameter. On pulling the colon out of the sac another loop of intestine was observed to have preceded the colon. It consisted of a portion of the transverse and descending colon, distended with gas; more highly inflamed, and approaching nearer to strangulation than the head of the colon. So that none of the contents could pass the constricted parts. After pulling out the second, a large portion of the omentum was found in the sac having been pushed up in by the loop of the former. The stomach was empty and not congested. The gall blader was filled with dark bile. The liver normal. The remaining portions of intestines not involved in the sac were not distended with gas and were pale and bloodless.

The hernial sac consisted of the peritoneal membrane, somewhat thickened, but having no adhesions to the abdominal viscera nor to the lungs. It seemed to have taken on an elasticity which allowed the sac to become largely distended without rupturing. The edges of the torn diaphragm were thickened and rounded, the sac gliding over the border easily.

I got the early history of this case from the wife of the patient. Nineteen years ago he had a very severe attack of vomiting, with colic, accompanied with distressed breathing and cough, which attack lasted him many days, but gradually recovered. He was ever after this subject to occasional attacks of colic with vomiting, cough and distressed breathing, but would recover from them in a few days. He was quite a hearty eater and his body was well nourished. About eight years ago he had cerebral hæmorrhage, followed by hemiphlegia of the left side, from which he readily recovered. There is no doubt about this hernia having existed nineteen years, yet the man was in tolerable good health except when he ate something which created gas in the intestines. The opening was too large to produce strangulation under ordinary circumstances.

I learned from the physicians who attended him, that over the region of hernia it was extremely tympanitic and painful. The case was regarded as one of "stoppage of the bowels." The question came up: Could laparotomy have relieved, and saved the patient? Of course the intestines in the sac could easily have been pulled out, the gas evacuated, and every thing gone on as usual, but during the healing of the abdominal wound, the intestines would again fill with gas, and float up into the sac.

ALCOHOL AND THE NERVE CENTRES.

Dr. Shorthouse has been investigating the effect of various intoxicating liquors on different parts of the cerebellum when imbibed not "wisely but too well." Dr. Shorthouse finds that good wine and beer indiscreetly imbibed have the effect of making a man fall on his side, whisky, and especially Irish whisky, on his face, and cider and perry, on his back, these disturbances of equilibrium corresponding exactly with those caused by injury to the lateral lobes and to the anterior and posterior parts of the middle lobe of the cerebellum respectively.

SOME NEW STUDIES OF THE OPIUM DISEASE.*

By T. D. CROTHERS, M. D.,
SUPT. WALNUT LODGE HOSPITAL, HARTFORD, CONN.

As a preface, I wish to express my emphatic dissent against the common use of the word *habit*, in describing the opium disease. The popular meaning conveyed by this term is some state or condition voluntarily acquired and retained with the certainty of being thrown off at any time at the will of the patient. This view assumes a knowledge of physiology and psychology of the brain and its functions that is not yet attained. Hence the use of the word is incorrect, wrong, and contradicted by the facts in the clinical history of each case. It also conveys a false impression of the nature and origin of such cases, and is a word to which different meanings will always be given. No other word is more misleading and confusing, when applied to opium, alcohol, and other borderland neuroses.

Beyond all question, the toxic use of opium and its alkaloids is rapidly increasing. Only about 50 per cent. of opium and morphine manufactured is required by the legitimate demands of medicine and pharmacy. The enormous balance is consumed in some unknown way. Comparative estimates make the number of opium cases in this country over a hundred thousand. Whether this is correct or not, it is evident that the number is very great and largely concealed, and many of them are very hopeless and difficult to treat. The natural history of such cases indicates a steady, progressive degeneration, on to death. Recovery is rarely spontaneous, and without the aid of applied science. Up to the present all clinical studies have been confined to the symptoms and treatment, starting from some indefinite point after the opium addiction begins. The old superstition of a moral origin, and some wilful, wicked impulse, is accepted as the first original cause. Writers, and even specialists, seldom go back into the early etiology, or inquire what conditions or forces led to the first use of opium. The object of this paper is to trace some recent facts which throw new light on this unknown stage of etiology.

From a careful clinical study and grouping of the history of a number of opium cases, it is evident that a large proportion have a distinct *neurotic diathesis*, or, more literally, have inherited from their parents some condition of brain and nerve defect which favors and predisposes to the development of neurotic diseases. A more careful study of these records shows that in some cases an *opium diathesis* is present, or a special inherited tendency to use opium. Here are two conditions which influence and favor this disease. It is a well-known fact that a large proportion of all nerve and brain diseases appears in children of neurotic and defective parents. Such children have received some special tendency and predisposition favoring the growth of nerve diseases, springing into activity from the slightest causes.

The latency or activity of this diathesis will depend on certain conditions of life and surroundings, which in many cases can be traced. In some instances the diseases of parents reappear in the children, in others in allied diseases, and not infrequently these defects pass over and reappear in the third generation. Often such defects are dormant, and only break out from the application of some peculiar exciting cause. Thus a hysteric mother and paranæic father were followed by three children. One was an alcoholic, the second was a wild, impulsive temperance reformer, the third was a sad, depressed, melancholic man. In the third generation opium and alcoholic inebriety, insanity, pauperism, also feebleness of mind and body, appeared. These varied forms of nerve diseases all had a neurotic diathesis as a basis, and the different phases were the direct result of different exciting causes. These facts are numerous and well attested, and so uniform in their operation that it is entirely within the realm of possibility to predict that, from a knowledge of the diseases of the parent and the environment of the child, certain forms of degeneration and diseases will appear with almost astronomical precision. This term neurotic diathesis covers a vast unknown field of causes which extend back many generations. The evolution of brain and nerve defects can often be traced through the realms of environment, nutrition, growth, and development. Medical text-books and teaching which fail to recognize this, give very narrow conceptions and strange exaggerations of the influence and force of many insignificant and secondary factors in the production of disease. The opium-taker has often this neurotic element in his history. It may be traced back to his ancestors, or it may be associated with brain or nerve injuries, cell-starvation, faulty nutrition, auto-intoxications, brain strains, or excessive drains of nerve force.

*Read before the Philadelphia County Medical Society, Jan. 27th, 1892.

A train of predisposing causes may have been gathering for an indefinite time back. Then comes the match which kindles or fires the train of *gathering forces.* This same train of exciting causes may not explode, because the germ soil is absent. Opium in all forms is given daily, and yet only a comparatively small number of cases become addicted to its use. Why should an increasing number of persons take opium continuously for the transient relief it gives? Why should the effects of this drug become so pleasing as to demand its increased use, irrespective of all consequences? The only explanation is the presence of a neurotic diathesis, either inherited or acquired. The existence of a special opium diathesis has been doubted with supercilious contempt by many writers. Any clinical study of cases will show the error of such doubt. The notes of a few cases which have recently come under observation are illustrations by no means uncommon, and indicate the concealed factors of disease in many instances:

In Case 1 the mother was a secret morphine-taker, the father was a hypochondriac and melancholy clergyman. Two children followed, who were highly educated and healthy. One, a boy, became a physician, and at thirty suddenly began to use morphine and soon became a chronic case. The other, a girl, was well up to her marriage at twenty-four, when she began to use opium, for no apparent reason.

Case 2, reported by the late Dr. Parrish. Both parents used opium for sleep and neuralgia, and died leaving three children under five years of age. They were brought up in temperate families, and had no knowledge of the opium addiction of their parents. One, at twenty, continued the use of morphine after it had been given for some intestinal trouble. The second child suffered from dysmenorrhœa and began to take morphine for this trouble, and became a morphine maniac. The third child was a druggist, who at thirty was a confirmed opium taker.

Case 3. Both parents were neurotic, and probably opium-takers. Both died, leaving an infant child which was excessively irritable and peevish. By accident, morphine was used as a remedy, and from thenceforth the child would become delirious unless morphine was given daily. All efforts to break up its use failed, and for five years increasing doses were used constantly until the child's death.

In Case 4, five children of unknown parentage were all opium takers; all lived in different conditions and had different occupations. Two began the use of opium from some bowel trouble. Two have been under treatment, and relapsed (?).

The relief which this drug brings on all occasions, and its impulsive use, are unmistakable indications of a distinct opiun diathesis. I believe a careful clinical study will reveal many such instances.

There is a large class of opium cases in which a complex diathesis exists—particularly following inebriety and various forms of brain exhaustion. Often alcoholics will use opium irregularly and transmit to their descendants a diathesis which very commonly favors the use of this drug. Thus the alcohol diathesis frequently becomes the opium craze, with but slight exposure. Both of these disorders are rapidly interchangeable. The children of opium-takers may turn to alcohol for relief, and *vice versa.* It is clear that the moderate use of alcohol produces a degree of degeneration that frequently appears in the next generation as predisposing causes to the opium or allied diseases. Clinical study of cases brings ample confirmation of this. The children of both alcohol and opium inebriates display many forms of brain degeneration. The paranæics, criminals, prostitutes, paupers, and the army of defects, all build up a diathesis and favoring soil for the opium craze. Descendants from such parents will always be markedly defective. They are noted by brain and nerve instability, hyperæsthesia, and tendency to exhaustion; also extreme pain from every degree of functional disturbance, with low powers of restoration, inability to bear pain, and suffering from mental changeability, impulsiveness, and drug credulity, etc.

These characteristics are prominent, and mark a neurosis that quickly merges into the opium disease. Yet a minority of these cases show a sensitiveness in the effects of opium that prevents them from using it. I have seen a neurotic patient become dangerously narcotized by the use of half a grain of solid opium. Some of the alcoholics and other narcomaniacs have exhibited an incompatibility to opium that is often startling. The emesis and prostration, and the brain-stimulation which approaches and becomes hyperæmia from one or more doses, are familiar to all. This intolerance precludes the use of the drug, and is recognized with alarm by the patient. On the other hand, when the effects are rapid and marked, relieving pain or restoring the disturbance of the functions with no other than a pleasing sense of rest and cure, a dangerous diathesis should be

suspected. While the physician recognizes the constitutional incompatibility in one case, he ought not to overlook the abnormal attractiveness of the drug in the other. The dose of morphine which gives the first complete rest, or calms the delirious excitement, or relieves the neuralgic pain or the digestive disturbance, soon calls for its repetition, and many physicians will unconsciously sanction and advise its use. Thus, far more fatal conditions are cultivated and roused into activity. In all neurotic cases, the use of opium in any form when given, should be concealed and watched with care. If a special predilection for this drug appears, equal care and skill should be exercised to divert and change it. Opium should only be used from a knowledge of the nature and character of the case. I have seen the most disastrous results from the reckless use of morphine with the needle. Recently, a man to whom morphine was intolerant was cut and stunned by a falling plank in the street. The surgeon gave him a hypodermic of morphine, and ordered him to the hospital. He died in a short time from opium neuroses. Police surgeons often make this mistake, giving morphine that from some unknown reason becomes fatal.

There is another class of opium-takers in which abnormal nutrition seems to be the most active factor in the causation. The neurotic or opium diathesis is not apparently present, and opium-taking dates from some nutrient disturbance. Such cases are very commonly sufferers from dyspepsia, derangement of the liver and bowels. They have a deranged appetite, headaches, cramps, thirst, and fever at times, with nausea. They are anæmic and hyperæsthetic, and complain of varied pains and neuralgias. These cases are evidently ill-nourished, and, in all probability, suffer from imperfect digestion, assimilation, and elimination of food products and waste material. Poisonous compounds and auto-intoxications form sources of serious trouble. The brain suffers from fatigue and pain, the cells are imperfectly nourished, and congestions, complex neuralgias, nerve irritation and instability follow. For this condition opium is almost a specific paralyzant. These cases are found among the over-fed, the under-fed, and those who neglect common hygienic rules of living. Cases of the over-fed are usually epicures, gormands, and persons living sedentary lives, and eating at all times and places. Dyspepsia and derangement of the bowels and kidneys make them drug-takers; then follows opium in some form. Defective elimination and auto-intoxications are always present. The under-fed are usually misers or persons very poor and very neglectful of themselves, or paranæics who have some food delusion. They are practically suffering from cell and tissue starvation and nutrient debility. The same dyspepsia and bowel derangements follow. Then follows drug-taking or special foods, and soon opium is discovered and adopted as a remedy. The same poisonous waste products appear from deranged assimilation; also, elimination and the nerve centres are deranged by these new and dangerous chemical compounds. The class of persons who, from simple neglect, become diseased are often the very poor and ignorant, or some division of the great army of borderliners, who live both mentally and physically on the very frontiers of sanity and insanity. Such persons clearly suffer from many and various forms of auto-intoxications, and this is proven inductively by the result of eliminative treatment. In all of these cases of nutrient neglect, many favoring conditions encourage the use of opium. These cases are numerous and comprise a large part of the invalids, hypochondriacs, and chronic drug-takers who are seen in our offices and at the dispensaries. They are all practically suffering from faulty assimilations, and faulty eliminations and the irritation of retained poisonous compounds. Opium is a remedy of positive force in covering up the protests of the defective cells and irritable nerves. Often these cases are concealed and are partly the result of previous disorder, and partially acquired from the effects of opium.

Next to this class of nutrient sufferers who become opium-takers, are those who have some entailment of disease or injury. In their history it will appear that some stage of invalidism was present, dating from brain, nerve or bodily injury. Fevers, heat, or sunstrokes, brain shocks from any source which are followed by unconsciousness, or marked mental perturbations, with exhaustion, and also a profound lowering of all the vital forces. These and other events have left damaged functional and organic activities, manifest in various neuralgias and physical disturbances.

The use of opium conceals and covers up this trouble. Many veterans of the late war have become opium maniacs for the relief of their pains and sufferings, and this is often concealed where it might possibly peril the procuring of a pension. The pension bureau should recognize the use of opium as a natural sequence and entailment following the disease and injury in the service. In Prussia

both alcohol and opium inebriety are treated as diseases when occurring in the army or civil service. The suffering and hardships growing out of the war has been the exciting cause of a great many opium cases. Many persons who have no special nerve diathesis in their history, after some severe illness, injury, or mental strain exhibit a degree of nerve instability and feebleness that is significant of serious organic change. Such persons manifest perversions of taste, with delusions of foods and medicines, and are on the border-lines of narcomania, ready to use any food or drugs which will bring even transient relief. The use of opium is always perilous. Why all these and similar cases do not become opium-takers, is owing to the absence of some diathesis inherited or acquired.

We can see some of the many complex causes favoring brain and nerve strain, with rapid exhaustion and degeneration, and the interchangeability of nerve diseases, in which the use of opium is only another form of the same disease. But we cannot yet trace the early causes and cell-conditions which develop the opium craze. This morbid impulse, like the delirious thirst for water on a desert plain, completely dominates all reason and so-called will-power, and every consideration of life and surroundings. It is more than an accident, more than a failure to reason and act wisely; it is a disease, an organized march of dissolution. The demand for opium is only a symptom; the removal of opium is not the cure. Some central brain-degeneration has begun and is going on. Narcomania, a morbid thirst for any solids or fluids that will produce neuroses, is the general name, and opium mania is only one member of this family.

In this study the fact is emphasized that the opium disease appears most frequently in persons who have a neurotic and opium diathesis, and also in persons who are suffering from nutrient disturbances, and those who are invalids or have some entailment of previous disease and injury; also that certain diseases and symptoms seem to furnish favoring soils for its growth and development. While these are but faint outlines of many unknown facts, they are urged as starting-points from which to base other and more accurate studies. The medical treatment from this point of view is very suggestive. Obviously the removal of the opium is not the cure. The various methods of removal detailed with great exactness, as if they would apply to each case, are unfortunate reflections of the failure of the writers, and are based on the assumption that all cases are the same, and the removal of opium is the great essential in the treatment. Basing the treatment on the clinical study of the case, it will be evident that where an opium diathesis exists, the withdrawal of opium should be very gradual. The treatment and surroundings should be arranged with great care and exactness. Such persons should live in an institution for years, or be under constant medical care. The danger of relapse and the future of such cases will depend entirely on the conditions of life and surroundings. Rapid reduction and any heroic treatment is never permanent, even with the consent of the patient. Specifics, faith cures, or any measures that promise speedy cures, are failures from the beginning. The road back to approximate health is straight and narrow, and only along lines of applied science. Where the history of a *neurotic diathesis* is present, the withdrawal of the opium should be equally slow.

More attention must be paid to the brain and nerve nutrition. The removal of opium may be followed by the appearance of very serious disorders, such as epilepsy, hysteria, complex neuralgias and paranæics phases, alcoholism, and various other neuroses. The slow withdrawal of opium enables one to discover and anticipate these neurotic troubles which have been masked before. In one case, suicidal melancholy; in another, hyperæmia of the brain, with delusions; in the third, irritation and delirium; in the fourth, hysterical spasms appeared when the opium was removed. I have seen two cases of general paralysis suddenly spring into great activity after the opium was taken away. This condition was not suspected before. Alcoholism is a very common sequel after the removal of the opium. *Cocaine, chloral,* and almost every drug that has narcotic properties, are also very common entailments. While these are extreme cases, they are likely to be formed at any time. Great care should be exercised in using other narcotics to lessen the irritation from the withdrawal of this drug. Foods and tonics should be given. These cases require the same general treatment as neurasthenia and other states of brain exhaustion. They are drug-takers, and will resort to anything for relief. They are secretive, and require more care and more mental remedies, with long, exact hygienic surroundings.

Where the opium addiction has apparently come from bad nutrition and faulty elimination, with auto-intoxication, the treatment is very hopeful. A long preliminary

course of baths, mineral waters, and tonics should precede the removal of opium. Then the opium may be removed at once, without the knowledge of the patient. In proper surroundings with frequent baths, little danger of relapse or suffering will follow. Careful study and treatment of nutrition and digestion will fully restore the case, and relapse seldom occurs except from failure or neglect of the surroundings.

In the last class, where opium is taken and apparently follows from the entailment of some injury or disease, or the exhaustion of old age, a preliminary period of treatment seems to be required. Often the opium can be abandoned at once for some milder narcotic, and from this by gradations, discontinued entirely. Full knowledge of the diseased states present will always suggest the lines of treatment. In some cases the opium should not be removed; its diminution and concealment is required. In others, its rapid removal is essential. Many varied and difficult questions will appear in these cases. The more accurately the diseased states, also predisposing and exciting causes, the diathesis, and varied influences which have caused opium to be used, are studied, the more accurate the treatment. As in many other diseases, the causes may be anticipated, also neutralized and prevented. Opium-taking should be seen as a symptom; remove or break up the cause, and this symptom disappears.

Routine treatment, either by slow or rapid reduction of the opium, is not wise. The substitution of other narcotics is equally unwise. In a number of cases the withdrawal of opium only unmasks more serious diseases, and is positively wrong. A case of general paresis is now under treatment for the opium addiction. Before this opium addiction began the patient caused great distress by his delusions and extravagantly strange conduct. This treatment was wrong. A rheumatic woman of seventy is going through the same course to be free from opium, which has made life tolerable for ten years past. The treatment of opium mania is something more than the application of means and remedies for withdrawal of the drug with the least suffering. The symptomatology and organic lesions often date back to other causes more complex than opium. The treatment must begin by their removal. The general or special diathesis must be treated; the nutritive disorders, intoxications, and starvations must be recognized and removed. The influence of pathological states from previous disease and injury must be ascertained and treated. The power of environment, climate, occupation, and idiosyncrasies are also powerful factors to be considered.

These are the essential facts and conditions which must enter into the practical treatment. Among the many important problems, that of prevention promises the greatest possibilities. A recognition of the neurotic diathesis and other predisposing causes would enable the physicians to successfully guard against its approach.

The successful *stamping* out of both this and the alcoholic disease will be a reality in the future.

It is evident that the opium disease is still a undiscovered country, and the few student experts have not yet passed beyond its frontiers. This disease is all about us and may invade our homes and firesides any time, and *hence* demands recognition and most careful study; above all, ethical and moral levels. Its laws of growth, development, treatment, and curability all follow the great highway of evolution and dissolution.—(*For discussion, see Society Reports.*)

BROMIDE OF BISMUTH.

This salt has several times been experimented with by physicians of our acquaintance. Small quantities of it were prepared for their use by allowing powdered bismuth and bromine to act together in presence of a little water, driving off the excess of bromine by a current of air and subliming, or rather distilling, the residue.

Victor Meyer has recently published a note on this compound (*Annalen*, 264, 122). He prepared it by gradually adding *finely* powdered bismuth to bromine contained in a retort.

The combination of the two elements takes place slowly, several days being required, at the ordinary temperature, to complete the reaction. The mixture is then distilled, bromine and bromide of bismuth passing over, and a considerable amount of bismuth remaining behind. The latter is again powdered and treated in the same manner. To obtain the bismuth bromide pure, it must be distilled several times. It is finally obtained as a handsome orange-red mass, of a radiately-crystalline or grape-like form. It can be boiled, without decomposition, for many hours, in a flask provided with an up right condenser. Its vapor is deep red, very much like that of suphur or phosphorus sulphide.—*Amer. Drug.*

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting January 27, 1892.

Dr. T. D. Crothers read a paper on "Some New Studies of the Opium Disease." (See p. 372.)

DISCUSSION.

Dr. Thomas J. Mays: This theme has been one of intense interest to me, but I do not feel prepared to discuss the subject. There is, however, one point to which I should like to refer, and that is the relation between opium-taking and pulmonary consumption. We know that there is a strong affinity between alcoholism and consumption, and I would ask Dr. Crothers whether he has observed a similar relation between opium-taking and pulmonary consumption.

Dr. Joseph Hoffman: Looking at this subject from the medical side, I would say that I have taken some trouble to ascertain the frequency with which opium is prescribed by the general practitioner. The ordinary prescription-file of the drug store will show that three out of five of the prescriptions contain opium in some form or other, and I think that more than a little of the responsibility for opium-eating lies at the physician's door. It is prescribed without any attempt at cure, for opium has few curative effects, especially in acute disease.

The question arises, When should opium be used in surgical work? In shock, opium will not effect a cure, except in so far as it relieves pain, and if pain is the only thing to be remedied, often we have the remedy in opium. In cases where the pain is self-limited there is a great divergence of opinion as to whether opium should be used or not. In abdominal surgery we must refuse to use it. In these cases opium, instead of being beneficial, is harmful. Although it lulls pain, it produces much after-discomfort. There may be cases in which you cannot do without it; these are the undiscovered cases of opium-eating. In these cases the surgeon has to choose the lesser of two evils. Opium is injurious not only from its physical effect, but also from its moral influence. Take a patient broken-down with pain, add the pain of operation, and give a drug which destroys the power of self-control, and you introduce a semi-hysterical element which causes unending trouble.

In surgery there are better anodynes than opium. I have found the hydro-bromate of hyoscine to be preferable; it does not cause constipation, and thereby increase the tympany, as does opium; its only bad effect is to diminish secretion. By avoiding the use of opium we secure benefit by toning up the patient. In shock, strychnine will at once put the patient to the point of enduring the pain without any subsequent discomfort.

Dr. M. Price: The responsibility of the opium habit can, I think, be referred directly back to the physician. He begins by relieving the pain, and not only does so, but tells the patient what he is using for that purpose. I cannot speak in regard to the neurotic diathesis, but some of the best developed, and apparently best balanced, patients that I have had, so far as external appearances were concerned, were addicted to the opium habit, and some of them are still addicted to it. If the physician is forced to give opium, he should give it secretly.

As has been said, opium, by its stupefying influence upon the nervous system, covers up and masks the symptoms. The physician also is lulled into a feeling of security, and does not recognize the destructive changes that are taking place, and is only awakened when he finds his patient absolutely dying. I have seen cases of appendicitis where the physician thought that the patient was improving, and yet the abdomen was full of pus and the patient dying. The opium had not only quieted the patient, but also lulled the doctor into a feeling of security. Not only in appendicitis, but in other surgical conditions, where the pain and discomfort is so great as to call for the use of opium, something should be done instead of giving opium, unless the patient is past relief; there opium is proper enough. In abdominal surgery we have come to the firm conviction that opium is uncalled for except where the opium habit has been established.

Dr. J. P. Crozer Griffith: I stand here to-night feeling somewhat alone, since I intend to take issue in some respects with what has already been said in the discussion, and to consider the matter from the standpoint of the physician, rather than that of the surgeon. I agree fully with nearly all that was told us in the papers of the evening regarding the dangers of opium, and assent as well to the statements of Drs. Price and Hoffman, that in nearly every case of the opium habit the physician is probably responsible. At the same time one cannot but be impressed with the feeling that one of

the laity, strolling in here to night, would leave with the thought that opium is an unmitigated evil, a drug which should never be employed under any circumstances whatever, inasmuch as it never did anything but harm. Every unprejudiced physician can only regard this as radically wrong. I say it after mature deliberation, and not on the spur of the moment, but still I say it, that were I compelled to select one drug from the entire list in the Pharmacopœia, and confine myself to its use alone, I would unhesitatingly choose opium.

And though in this I am at variance with what we so often hear uttered in discussions in this Society, yet I trust I am not an antiquated fogy, and I know I try to keep abreast of the times. It has been urged that opium rarely cures disease, but only relieves symptoms, at the same time that it disguises them. I should like to inquire how many drugs in the Pharmacopœia really cure; certainly there are very few. As educated physicians, we hesitate to say that we have *cured* our patients. All that we expect to do is to guide our cases to recovery. I have no reference in this connection to the employment of surgical interference. Were it true that opium never had any powers but those of relief, there would, therefore, be no objection to its use on this score. Well aware of the dangers of the opium habit, I would hesitate long before beginning the employment of the drug in cases which were certain to run a somewhat chronic course, yet in which there was hope of recovery. Dujardin-Beaumetz has made the statement that thirty days' continuous use of opium will make an habitué of anyone. In the light of what has been said in the latter of the two papers of the evening, this is, perhaps, an over-statement. It at least expresses the opinion of an excellent French authority.

There are cases in which the greatest fanatic will probably admit that it is our duty to administer opium in some form. Among these are hopeless cases of cancer. It is true that the drug gradually loses its effect, and that the dose must constantly be increased. But in no other way can existence be made even tolerable. I believe, too, that it is almost a sin to omit the employment of opium in the last stages of many cases of phthisis. The statement has been made in text-books that opium is poison to patients with phthisis. While this may be true in theory, it is eminently untrue in practice. Of course, I have no reference to phthisis in the early stage. There is no question that in this stage we should defer employing it, trying other measures for relief, and devoting our attention to the cure of the disease.

While it is true that opium may occasionally cause—perhaps it is better to say *be followed by*—suppression of urine, dyspnœa. and other unpleasant and dangerous symptoms, we should not totally abandon its employment on this account. I have a patient in whom five drops of tincture of nux vomica is always followed by unpleasant evidences of the physiological action of strychnine, but I shall not on that account refuse to give nux vomica in other cases. I have seen retention of urine follow the application of turpentine stupes, but shall not for that reason abandon their use. So numerous drug-idiosyncrasies exist, that the man who inordinately fears them will never give anything, and had better retire from the profession.

As there are a number of gynæcologists present, I am ready to admit at once that I understand very little about abdominal surgery. But as a physician it is my duty to have some opinions about peritonitis. In former years, before the diagnosis of pathological conditions of the abdomen had so degenerated that it became necessary to cut the patient open in order to discover what was the matter, there were physicians who possessed sufficient diagnostic acumen to recognize peritonitis without this interior inspection. Dr. Alonzo Clark was one of these. Unfortunately for him, he died before he had the full opportunity of learning from the later lights concerning the avoidance of opium in peritonitis and the proper treatment of the affection, and he claimed that in some way it was partially curative. It was his custom to administer opium in very large doses in this disease. Doubtless it was very stupid of him to persist in this practice, but strange to say his cases recovered. It may, after all, not appear so strange when we call to mind that the use of depletives in peritonitis, including laxatives in some cases, had been in vogue up to that time, and with results far inferior to those of Dr. Clark's. For my part, I have yet to hear of any method of treatment which supersedes the administration of opium in this affection—not as a calmative agent, but as a curative one as well. Of course, there are cases in which every physician would counsel operation; but this is in no wise a sanction to indiscriminate laparotomy.

With regard to what has been said about opium in peritonitis beguiling the physician into a sense of false security, it is, of course, necessary that the attendant should have his wits about him, and realize that the drug is

liable to disguise the symptoms by relieving pain. I think, however, that there are other factors than the sensation of pain to indicate the existence of danger-signals.

Then, again, we must not forget that it is often impossible to obtain consent for an operation, however desirable this procedure may appear. In such cases we wish to be familiar with some method of treatment other than the employment of the knife. We shall sometimes be surprised by the recovery under the administration of opium of cases which we deemed hopeless without operation.

Dr. W. M. Capp: It is to be remembered that the physician is often hurriedly summoned to patients with acute symptoms and in great suffering, and it is from these that relief is sought. Generally speaking, it is well to say that we should sit down and study the case, to discover the cause of the suffering, and remove it, so that relief will naturally follow; but practically something more speedy is demanded, and a narcotic may be useful to tide the patient over what would be a critical period of suffering.

Dr. Crothers's paper was very interesting, but I do not know that we can agree with him in substituting the word disease for the word habit in all cases of opium addiction. I think that in many cases the use of opium is simply a habit, in no respect different from the alcohol or the tobacco habit. There are some persons with such weak will-power that they go through life dominated by a habit of some kind. The remark that the physician is largely responsible for the prevalence of the *improper* use of opium is rather too general. It is too sweeping an assertion to say that the physicians are responsible in all cases. It has also been intimated that from the frequency with which opium is prescribed we can easily account for the large quantity which is imported. This is too broad a statement to emanate from a society of this kind. Let me refer to one single fact. It is generally known that almost all patent medicines contain opium, and that there is no country in which so large a quantity of these nostrums is consumed. In their manufacture a large quantity of this drug is used, and it is but a short step from the use of narcotic patent medicines to the direct use of opium. There are many ways other than by the prescriptions of physicians by which people become addicted to the use of opium.

Dr. Edward Jackson: The power of opium to cover up symptoms has been mentioned. This is something more than the power to prevent pain by an action on the peripheral nerves or on the centres themselves. I have seen this illustrated in some cases of insufficiency of the eye muscles. I have one patient with hyperphoria of six centrads, who has suffered much from headache and other effects of eye-strain. If she takes three-fourths of a grain of opium, the hyperphoria entirely disappears. She is not hysterical and is not an opium habitué; she goes many weeks and even months without a single dose. For several hours after taking the opium the conditions of nervous action are so radically changed that the hyperphoria no longer exists, so far as we can in any way discover it. My attention was called to a similar case by my friend, Dr. Charles H. Thomas. In these cases there is certainly some peculiar effect on the coördination of nerve impulses, so that both the pain and also its cause are for the time removed.

In regard to the lessened importation of opium, it occurred to me that this might be connected with the introduction of hyosine and some of the coal-tar derivatives, and their wide use by both the profession and laity; also with the attack led by the abdominal surgeons on the use of opium in what was formerly regarded as its peculiar province, the abdominal inflammations.

Dr. William H. Welch: A celebrated physician of this city once said he could count on the fingers of one hand all the drugs that he had found of real use in his practice, and he would place opium at the head of the list. Now I feel very much the same way. Of course, I recognize the fact that opium, like alcohol, is greatly abused; but I would not be willing to give up either on that account. I have met with a number of persons who have become habituated to the use of opium, but I have seen only one case in which I have aided in breaking off the use of the drug. This patient was a nurse, who had contracted the habit voluntarily. He began the use of morphine to induce sleep, after having met with a bereavement in his family. I think he also suffered from neuralgia. He gradually increased the dose up to two grains a day. After continuing this for two years he decided to give it up, and so he gradually diminished the daily dose for four days, when he discontinued entirely. To relieve the pain in his extremities, he took antipyrine and also bromide of sodium to promote sleep. After abstaining from its use for several months, he went on a visit to New York, and while there was taken with cholera morbus. He applied to the nearest drug-store for relief, and the druggist gave him a mixture contain-

ing opium in some form. From this time he returned to the use of morphine, and soon reached a daily dose of four grains. After continuing the use of the drug now for two years longer, he again resolved to break off the habit, and this time placed himself under my care. It is unnecessary to recite in detail the symptoms that followed, but the extreme muscular weakness was very surprising, especially when we consider that the daily dose was only four grains. In a few days after discontinuing the drug he became absolutely helpless; he could not feed himself, and could not hold in his hand even a glass of water. He became delirious. In the course of two weeks he began to improve, but it was three weeks before he was able to resume his duties. I should add that he took bromide of sodium very freely, and some critics have suggested that the extreme muscular weakness may have been due to this drug. He, however, showed the weakness before the bromide was taken. He took as much as two hundred and forty grains of the bromide daily for several days. I know nothing of his family history, but so far as the individual himself is concerned, there appears to be no neurotic element in the case. It has now been two years since he stopped the drug, and he tells me he has not returned to its use. But these people often practise so much deception that I cannot be absolutely sure on this point.

Dr. T. B. Schneidemann: I recall a valuable little book, now out of print, by Professor Fiske, of Harvard, on alcohol and tobacco. The title-page bears the legends, "I. It Does Pay to Smoke." "II. The Coming Man will Drink Wine." The author is at some pains to define the difference between a stimulant dose and a narcotic dose, the former being such an amount as nourishes or facilitates the normal nutrition of the nervous system, restoring its equilibrium, enabling it with diminished effort to discharge its natural functions. Such a dose, moreover, has no evil after-effect—"reaction"—which belongs only to a narcotic dose, the term over-stimulation being a misnomer, and imported into physiology from *à priori* reasoning. As a stimulant, he declares that these substances diminish the friction of life, and are useful adjuncts to civilization, and that the dose does not have to be increased, and that their use may be dispensed with at any time without exciting morbid craving. Fiske's views are essentially those of Anstie.

Dr. T. Ridgway Barker: There is one point in Dr. Crother's paper that impressed me, and that is the importance of hereditary predisposition. This belongs to what is known as the interchangeable neuroses. If the histories of cases are more carefully examined, we shall find that inherited tendencies have a great deal to do with the use of narcotics and stimulants.

I think the physician should not wholly escape from the charge of too frequently prescribing morphine and other narcotics. It is not uncommon in cases associated with pain for the physician to take from his hypodermatic case tablets of morphine, and instruct the patient to take one every hour or so, according to circumstances. The patient is aware of the nature of the drug and may acquire the habit.

In cases of post-partum hæmorrhage one-drachm doses of tincture of opium certainly have a happy effect. Even where the patient is almost exsanguined, she may recover.

I was glad to hear the recommendation of Dr. Crothers in regard to the gradual diminution of the dose, thus disturbing less markedly the nervous system.

Dr. Hoffman: Very little weight can be attached to the recommendations or argument that certain men used opium twenty or twenty-five years ago with good results. There is no doubt that in certain acute painful diseases opium is indicated, as in rheumatism, the passage of a stone, and in neuralgia. When the surgeon talks about peritonitis, he talks about something he knows, while the general practitioner talks about something he imagines. Nine-tenths of the cases of so-called peritonitis are not peritonitis at all. When the abdominal surgeon opens the abdomen, he makes a peritonitis, for the reparation is due to inflammation. In these cases, no matter how great the swelling and pain, it passes away under the use of salines or calomel. I think that here we have the vantage ground of the argument, for we know what we have done, and we have the results.

Dr. M. Price: I should like to call attention to the statement in regard to the general practitioner and peritonitis, When the physician gets a case of peritonitis that he thinks is going to die, he refers it to the surgeon. The very men who are boasting of their twenty or thirty cures of peritonitis are the men who are referring to the surgeon their fatal cases with quarts of pus in the abdomen. When we cure from 93 to 97 per cent. of the cases that they give up, I think that we have the best of the argument. A case was recently reported from Buffalo of a girl ten years of age treated with mor-

phine for fourteen days, the daily dose finally reaching twenty-five grains. The temperature had disappeared five days before this dose was reached. They then gave her a saline; they had given salines before, but the child vomited it. I cannot understand such peritonitis. Here must be some neuralgic or nervous condition mistaken for peritonitis.

Dr. Werner: The remarks of Dr. Crothers seem to reinforce my position, that when indicated opium should be given with great care, and in such a way that the patient does not know that he is taking opium. Some years ago I was called to see a child one month old. I found it in convulsions, with contracted pupils; the child had previously been well. I asked if they had given any medicine. They at first denied that they had, but subsequently admitted that a neighbor had given the child a dose of medicine for colic. The child died in less than twenty-four hours, and subsequent investigation showed that it had received an eighth of a grain of morphine.

Another case I recall is that of a young girl of strumous diathesis, who had been treated for various troubles, and finally, going to a gynæcologist, a stem pessary was introduced. She came to me, I removed the pessary, and found the uterus and broad ligaments swollen and extremely sensitive; there was menstrual pain. She was placed at rest, with suitable treatment and improved. Being a working girl, she is compelled to be much on her feet, and soon all the old pains returned. I told her that if she could rest she might be comfortable, but that otherwise it would be necessary to remove the diseased appendages. She refused operation, and the last time I saw her she told me a friend promised to give her some powders, which she thought contained morphine. I explained the dangers to her, but in spite of that she is takling the morphine; I do not know what the result will be.

These cases are sufficient to show the necessity of calling a halt. Prescriptions should not be allowed to be renewed at random. The cases for the use of opium are rare, and should be carefully selected, and the physician should give the dose himself.

I fully agree with the remarks made by Drs. Price and Hoffman regarding the use of opium in abdominal work, and feel certain that many lives are saved by having given up its use; it has certainly often lulled both patient and physician into a dangerous feeling of security until it was too late. I recall one case of septic peritonitis, which I saw in consultation. Although the patient was comfortable after calomel and salines, I knew from the pulse and temperature that there was pus, and suggested operation. The family physician refused operation unless I could show him that pus was present. I agreed to remain in attendance, provided opium was not given. On Wednesday he gave the first dose of opium, for what reason I do not know; there was no pain and there were daily movements. After the opium, distension of the abdomen occurred, and death the following Sunday. In these days, when we are trying to have cleanliness in everything, why should we shrink from giving salines and clearing the bowel of any foul material? Why should we block the bowels with opium when we know that the products are reabsorbed? These are questions I should be glad to have answered from the other side.

Dr. Crothers, of Hartford, Conn.: The interest which this subject has excited is very pleasing to me. The point which I tried to make clear is that these are neurotic cases, either acquired or inherited, and that we should treat them as such, and bear this fact in mind in our use of opium. If we have a neurotic case, we should remember this predilection to the opium habit.

Dr. Mays was among the pioneers who exemplied the close connection between alcoholism and consumption, and between opium-taking and consumption. Phthisis, alcoholism, opium-taking and a host of other affections,are neurotic conditions, and interchangeable one with the other.

I have strongly objected to the word habit, because its exact meaning is not understood. We use the word in its common sense and not in its scientific sense.

There are many reasons for the discrepancy between the quantity of opium imported and the quantity used legitimately. It shows that opium-taking is increasing, and that opium is used in various secretive ways.

I think that there are no physicians in general practice who will not regard opium as a bad remedy. I think that the statement that it is one of our chief remedies will be confirmed by all. It is, however, clear that it should be given with great caution and its use concealed from the patient's knowledge. We cannot dispense with it under any circumstances. My principal point has been to call attention to the neurotic character of these cases and not to disparage the use of opium.

With regard to the treatment of opium cases, we come to a wide field which the general practioner is not quite ready to enter. The routine treatment of diminishing the

quantity of opium as the only plan of cure employed must be abandoned. Opium must be retained or diminished according to the case. In some cases it would shorten life if the opium were diminished. In the large proportion of cases, however, the opium can be removed. The routine plan of diminishing the opium gradually or rapidly is largely empirical. No one should undertake the opium-treatment without knowing the dia thesis and condition of his case, and then the question of the remeval or diminution of the opium becomes clear and the result satisfactory.

SELECTED FORMULÆ.

THE KEELEY CURE.

Dr. H. E. Whitsey writes to the *Medical World* that the following produces a mixture which comes very close to the much-vaunted one used by Keeley:

℞
Sodio-auric chloride.....gr. xij.
Ammonium chloride.....gr. vj.
Strychnine nitrate.....gr. j.
Atropine.....gr. ¼.
Extract cinchona comp. fluid.....ʒ iij.
Extract coca fluid.....ʒ j.
Glycerine.....ʒ j.
Water.....ʒ j.

M. Sig. Take a teaspoonful every two houra when awake. And the following hypodermic injection every four hours: 1-10 grain of the chloride of gold and sodium and 1-40 grain of the nitrate of strychniue.

This will produce the same symptoms and same results as the Keeley cure.

ECZEMA.

℞
Papoid.....gr. xij.
Pulv. boracic acid.....gr. v.
Aquæ destil.....ʒ ij.

Ft. solution. Sig. To be painted on the parts twice daily.

This is a successful application in cases of eczema, psoriasis and callosities of the epidermis.

LOCAL ANÆSTHESIA FOR SLIGHT OPERATIONS.

℞
Chloroform.....10 parts.
Sulphuric ether.....15 "
Menthol..... 1 "

M. Sig. To be used with an atomizer. The anæsthesia lasts from two to ten minutes.

—*Medical News.*

ACUTE TONSILLITIS.

Dr. A. Martin (*La Semaine médicale*, No. 55, 1891) speaks highly of the following:

℞
Acid carbolic, } .....āā gramme 1.
Camphor, }
Glycerine, } .....āā grammes 50.
Aq. destillat., }

Three or four local applications a day.

ECZEMA OF THE ANUS AND SCROTUM

Unna recommends the following:

℞
Olei lini.,
Aquæ calcis,
Zinci oxidi.....āā ʒ j.
Iodoformi.....ʒ ss.

M. Sig. Apply locally.

—*L'Union Médicale.*

CHRONIC DIARRHŒA WITH INTESTINAL FERMENTATION.

℞
Salol..... 3 parts.
Ol. ricini..... 15 "
Symp rhei..... 30 "
Gum arabic qs.,
Aquæ destil.....120 "

M. S. Tablespoonful every hour till bowels move.

—*Le Prog. Med.*

HÆMOPTYSIS.

(PEPPER.)

℞
Acidi gallici.....2 drams.
Acid sulph. aromat.....1 dram.
Glycerine.....1 ounce.
Aq. dest., enough for.....4 ounces.

M. Sig. Teaspoonful at dose—re, eat frequently.

NERVOUS COUGH.

Prof. Bartholow frequently orders:

℞
Acidi hydrocyanic dil.....ʒ j.
Tinct. sanguinariæ.....ʒ ss.
Syr. senegæ.....ʒ iv.
Aquæ lauro-cerasi.....ʒ vij.
Syr. tolu.....ʒ ij.

M. Sig. From ten drops to a teaspoonful every four hours, according to the age of the patient.

ERYSIPELIS.

℞
Acid carbolic.....½ drachm.
Tr. iodine.....½ "
Alcohol.....½ "
Turpentine.....1 ounce.
Glycerin.....3 ounces.

M. Sig. Apply with camel's hair pencil several times daily, or on a soft cloth.

—*Ind. Pharm.*

ANTISEPTIC TREATMENT OF CHRONIC DIARRHŒA.

This consists in the employment of enemata of salicylic acid solutions and in the administration of rhubarb by the mouth.

℞
Acid salicyl.....gramme 1.
Aquæ destil.....grammes 500.
Alcohol, q. s.

M. Sig. For one rectal injection.

This is injected through a long tube. The injection is repeated several times a day.

The formula containing the rhubarb is as follows:

℞
Salol.....grammes 4.
Ol. ricini..... " 20.
Syrup. rhei..... " 40.
Aquæ cinnamon..... " 150.
Gum arabic, q. s.

M. Sig. Tablespoonful every hour till the effect is produced.

For diet, milk, eggs, etc., are ordered.—*France Med.—Rev. Int. Bib.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)
PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter. each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1,50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

LEADING ARTICLE.

CHLORALAMIDE AS A HYPNOTIC.

The powerful hypnotic properties of chloral have rendered it one of the most valuable agents in the Pharmacopœia, but its use has been restricted, owing chiefly to its decided depressant action on the circulation and the consequent serious results that have from time to time been observed. A number of endeavors have been made to so modify the chloral molecule that its hypnotic properties should be retained and other undesirable actions eliminated, as well to add some new and desirable actions. During the last few years we have had offered to us a number of such compounds, notably among them being *somnal, hypnal* and *chloralamide.* Somnal is a liquid discovered by Radlauer, who claims it to be a distinct chemical compound resulting from the mixture of chloral, alcohol and urethane, and to have the formula of $C_7H_{12}Cl_3O_3N$. Hypnal is a combination of chloral and antipyrine molecules, and is chemically a mono-chloral-antipyrine. Chloralamide was introduced by Mering. It was hoped by the introduction of an amide molecule into that of chloral that the depressant effects of the latter upon the circulation might be replaced by those of the opposite character of ammonia. Since formamide contained the largest amount of ammonia of all the amides it was selected, and upon being mixed with chloral-anhydride gives rise to chloralamide, or what is properly speaking chloral-formamide.

The first reports of the clinical use of this substance appeared in August, 1889, and since that time sufficient statistics have accumulated to enable us to reach fairly definite conclusions as to its probable value in clinical medicine. Without mentioning isolated cases we will refer to the results of a number of investigations which have a special value chiefly owing to the large number of cases studied.

Hagen and Hüfler employed it 118 times in twenty-four sick and four healthy persons. Twenty-six of the number on whom the

drug was tried gave good results. The doses ranged from thirty to forty-five grains. Women appeared to be more susceptible than men. As a result of these observations they concluded that chloralamide was a powerful hypnotic and equal to chloral. In one case they noted collapse. Reichmann found that two or three grammes were sufficient to produce deep sleep. Rabow employed it in fifty-two instances, and in but few was there any failure or unpleasant after-effects. Peiper used seventy-six doses in twenty-four cases, and states that he found it a good hypnotic, but not absolutely reliable; that its action begins within thirty or forty minutes after the dose; that it is of value in a large range of cases; that children are very susceptible to it; and that headache, vertigo and weakness of the joints occasionally are sequelæ. Alt noted twelve failures in forty-one cases.

Halasy, from an experience of one hundred and ninety-one administrations in thirty-five persons with various maladies, concluded, that chloralamide is a good hypnotic, but not absolutely sure in its action; that in cases of insomnia caused by pain or cough it is rarely efficient; that it exercises an unfavorable effect on the heart and circulation; that it cannot be prescribed with safety in cardiac lesions; that its ingestion is sometimes followed by disagreeable secondary symptoms, such as headache, vertigo, lassitude and dryness of the throat, although none of a serious character; and that in some cases it induces disorders of digestion and vomiting. He did not observe any cumulative action.

Osler used it in fifty cases to which one hundred and eighty-six doses were given. Forty were poor sleepers, and ten were not troubled with sleeplessness. The list of diseases with which some of these individuals were affected embraced phthisis, cardiac disease, chronic nervous affections, diabetes, aneurism, typhoid fever, pneumonia, bronchitis, etc. The dose varied from ten to sixty grains, both in single and divided doses. The results he classifies under three heads: those in which there was an undoubted hypnotic action; those in which the action was uncertain; and those in which the results were unmistakably negative. Of the one hundred and eighty-six trials, eighty-six, or 46.32 per cent., showed positive results; eighty-five administrations, or 45.69 per cent., gave results of a doubtful character; and in fifteen trials the results were uncertain. In sixteen instances ill effects followed—headache in eight, a sense of being dazed and confused in four, and in two, mental derangement. Sleep followed within an hour, and generally within half an hour, in nearly every positive case. No cumulative action was noticed.

Robinson gave one hundred and fifty administrations in fifty persons. In thirteen the effect was good, in fourteen, passable, and in twenty-three, negative.

W. Hale White used it in twenty patients suffering from various illnesses, in all of whom insomnia was a troublesome symptom. The drug produced comfortable sleep in all the cases except two; one of these was suffering from delirium associated with cerebral hæmorrhage, and the other had rheumatic fever complicated with delirium tremens and salicylic acid poisoning. Both these patients died shortly after admission. Some of the other cases had extremely painful diseases, and yet chloralamide produced sleep. One woman who had a thoracic aneurism preferred it to morphine, and another patient who had carcinoma of the stomach also slept better with this drug than with morphine. The patient with carcinoma suffered intense pain, yet dozed comfortably after chloralamide. In general, both he and the attendants in the hospital found that the patients slept better after chloralamide than after any of the recently introduced hypnotics. In none of the twenty cases did any ill effects follow which could be looked upon as contra-indicating its use, nor did he ever observe any depressing results. The time elapsing between its administration and the beginning of sleep varied between a quarter of an hour and two or three hours. When given in the evening, the patient when once asleep usually slept till morning. Dr. White has noted, as have certain others, that after a dose in the

evening the patient sometimes does not go to sleep until the next morning, and then remains asleep all day. The reason for this action, he thinks, is to be found in a slow absorption owing to the feeble solubility of the drug in water (five hours are required to disolve twenty grains in two ounces of water). He always prescribes it with spirit—twenty grains are dissolved by one drachm of rectified spirit in fifteen minutes, and water may be added to this solution without precipitating the chloralamide. A good way of giving it is to dissolve it in a little brandy, add water to the liking of the patient, and drink shortly before going to bed. He also calls attention to the important fact that if given in milk, it is not only insoluble, but sticks to the sides and bottom of the glass, and is troublesome to swallow. Moreover, it should never be prescribed with alkalies or dissolved in hot water. Thirty grains he usually found sufficient. As a result of these trials he thinks that in chloralamide we have a safe hypnotic, which has hardly ever any depressing action, and which very rarely gives rise to any unpleasant after-effects.

Gerisch prescribed chloralamide in thirty-two cases, giving thirty grains at night. This dose was usually sufficient to induce sleep within a half hour. A more certain effect and longer sleep was obtained when forty-five to sixty grains were given. He considers chloralamide very valuable because of its decisiveness and the absence of unpleasantness. In sleeplessness due to pain, he states that the effects were negative. He also believes that it is not a dangerous body, but that headache and vomiting may occur after a very large dose. Digestion and the renal function were not affected, but the pulse generally became softer and more frequent. Umpfenbach employed it in fifty-five cases, twenty-three of which were men and the remainder women. In the greater number of them the results were everything that could be desired, although the symptoms in some cases were very severe. Considerable importance rests with the fact that in every instance the drug was well borne, even when taken for months together. No action on the circulation or genito-urinary system was detected, nor were there any symptoms of collapse. In one case it acted as an excitant. On the whole, he looks upon it as a decidedly useful hypnotic. In the insane wards of the Philadelphia Hospital it has had extensive use with the most satisfactory results.

Recently, Gordon has added a valuable contribution to the literature of this subject. His studies were made both on the lower animals and man. The following summary embodies the chief results of his observations:

1. The reflex irritability of the spinal cord was diminished. 2. Peripheral sensation was not reduced. 3. On frogs there were hypnotic action, slowed respiratory and cardiac actions, abolition of reflexes, and subsequent recovery of the normal condition. 4. Blood pressure was slowly reduced with large doses. 5. Pulse-rate was not affected. 6. Respirations were reduced and finally abolished. 7. The conductivity of motor nerves was destroyed, and was not restored by subsequent washing in salt solution. 8. The irritability of muscle substance was destroyed, and was not restored by subsequent washing in salt solution. 9. The excretion of urea was increased by small doses—0.3 to 0.6 gramme—but was diminished by large doses—2 to 3 grammes. 10. The excretion of phosphates was diminished with both large and small doses. 11. The excretion of the fluid constituents of the urine was not constantly affected by the smaller doses, but was diminished by the larger doses. 12. Reaction of urine was not influenced. 13. Color and odor of urine were not affected. 14. No albumen was detected. 15. Action on the skin was negative. 16. Temperature was not affected. 17. Digestion did not appear to be interfered with. 18. Hypnotic action in the healthy was induced with doses of 1.25 gramme and upward. 19. In painless insomnia the results were highly reliable. 20. In insomnia with moderate pain the results were fairly reliable. 21. In insomnia with acute pain it was not reliable. 22. The analgesic action was feeble. 23. The hypnotic effect followed usually within half an hour after exhibition. 24.

The sleep induced was tranquil, pleasant, and natural, and the awakening free from confusion or depression. 25. No deferred action. 26. No craving for the drug was noticed. 27. The point of tolerance was not readily reached. 28. The doses found most reliable were from 2 to 3 grammes. 29. Giddiness and incoördination and headache sometimes followed administration. 30. In senile insomnia, pulmonary diseases and hysteria the results were highly satisfactory.

Finally, we will refer to the experimental research of Prof. H. C. Wood and Dr. David Cerna. Their investigations were made solely on dogs, and their conclusions are as follows: Chloralamid has a slight local influence, and in large doses tends to produce mucous diarrhœa. It acts more powerfully upon the cerebral cortex than upon any other portion of the nervous system of voluntary life, thereby causing sleep and muscular relaxation; but it is also a feeble spinal depressant. It has a powerful influence upon the respiration, in moderate dose, by a centric action stimulating the respiratory-rate, and probably also increasing the actual amount of air breathed; but in toxic dose causing death by paralysis. Its influence upon the circulation is a very feeble one; the changes produced by small doses being probably secondary to other effects of the drug; toxic doses, however, depress the arterial pressure by direct action either upon the heart or upon the muscle coats in the arterioles. The results of their experiments indicate that chloralamide is very worthy of trial as a hypnotic. Its action upon the heart is so slight that it bids fair to be valuable as a hypnotic in cases of feeble heart; whilst its stimulating influence upon the respiration would seem to fit it for employment in cases of nervous exhaustion. Dr. H. C. Wood has used the remedy to a moderate extent in various forms of insomnia, and so far it has seemed to be slower and less certain in its action than is chloral. Rarely have unpleasant after-effects been noted, but he has seen in some cases distinct headache. The statement of Hagen and Hüfler that the drug is especially valuable in cardiac asthma seems to be consonant with Wood and Cerna's experimental conclusions.

While the results of the above investigations are by no means in strict accord, they are as consonant as could be hoped considering the indiscriminate use to which the drug has been put, and are, as a whole, no more discrepant than those obtained during the early clinical investigations with most therapeutic agents. A careful survey of these contributions in connection with many others not noted, shows that the more recent records place chloralamide on a very satisfactory basis; in other words, the clinician is learning in what cases this new hypnotic may be expected to afford entirely satisfactory results.

The clinical value of chloralamide is obviously largely to be determined by its efficiency compared with chloral, which it is intended to replace. Certainly we find in it essentially the same physiological characteristics, some of which being noticeably modified. Like chloral it is a hypnotic with feeble analgesic powers. It is a circulatory depressant, but feebler in its action, and is to be cautiously employed in conditions of circulatory depression. It seems undoubtedly less powerful and prompt in its actions than chloral, but, on the other hand, it is, perhaps, quite as certain. It, like chloral, may give rise to secondary symptoms, such as headache, vertigo, weakness, dryness of the throat, epistaxis, disorders of digestion, vomiting, collapse, mental derangement, etc. Children and women seem more susceptible to it than men. There seems to be no cumulative action; it is in most cases of no value where sleeplessness is dependent upon or associated with much pain; it is absorbed with relative slowness, the action beginning within 30 or 40 minutes; it is best given dissolved in a little brandy with sufficient water; it should never be given with milk, alkalies or hot water.

In conclusion, the actions of choralamide and chloral are essentially identical in character; chloralamide is less powerful and prompt as a hypnotic, but certainly acts less deleteriously on circulation—hence, it may be used with equal satisfaction in most

of the cases where chloral is indicated, and in many in which the latter would not be safe. Chloralamide is certainly deserving of intelligent and thorough investigation, and will doubtless prove a valuable and permanent addition to our materia medica.

BOOK REVIEWS.

DISEASES OF THE MOUTH IN CHILDREN, (Non-surgical), by F. Forchheimer, M. D., Philadelphia. J. B. Lippincott & Co., 1892.

Prof. Forchheimer has brought together in book form, with suitable amplifications, his admirable and much commended essays on diseases of the mouth in children, which appeared in the *Archives of Pediatrics*. His persistent work in this direction and tireless calling attention to the woeful chaos of nomenclature, of pathological misconceptions and symptomatic misapprehensions, resulted in the appointment of a special committee by the President of the American Pediatric Association to revise all this. If he does no other thing of note in his professional career than to have written this excellent book, he will have earned a well deserved meed of praise at the hands of all medical practitioners.

He has made thoroughly comprehensible those not serious but ever present woes of the mouth, next to the stomach the most important part of young children, which rarely jeopardise life, but add so much to their discomfort (and to the solicitous household). He impresses the readers of his book with a determination to explore that prominent cavity with the confident expection of finding many things clear which aforetime were wrapped in doubt and obscurity.

Hereafter no writer on children's maladies, systematic or discursive, will have excuse to ignore or even fail to follow his simple classification, nor need we vex ourselves with the numberless *words* which served to hide so effectually the ignorance of those who follow old trails, nor fail to look for the lesion where it may reasonably be expected to be found. Thereupon, no longer need treatment be tentative and experimental.

Prof. Forchheimer, however, begins at the beginning, the origin of all successful medical thought, more especially, too, in infantile ailments, by a fundamental knowledge based on physiology, holding as he does that chair, as well as of Clinical Diseases of Children in the University of Ohio.

He is to be congratulated on having in the little volume of scarce two hundred pages made clear as noonday a subject till now burdened with effete and conflicting views.

CONSUMPTION—HOW TO PREVENT IT AND HOW TO LIVE WITH IT. By N. S. Davis, Jr., A. M., M. D., Professor of Principles and Practice of Medicine, Chicago, Ill., etc. F. A. Davis, publisher, Philadelphia and London, 1891. Price, 75 cents.

The difficulty in getting consumptives to observe proper sanitation and to carry out certain rules which are more or less in the nature of necessity for successful treatment, is the experience of every physician having anything to do with the management of this class of cases. This is due to some extent, as Dr. Davis intimates, to the difficulty of impressing by brief conversations the recognition of certain facts which are indispensable for their patients' welfare. This led the author to prepare for his patients a series of hygienic rules with brief explanations of their effect and their execution. From these rules this book has grown. It will be observed that Dr. Davis has written for the laity.

The author treats seriatim of the nature of the disease; Nature's means of preventing infection, and predisposition; various means of prevention; hygiene for the consumptive; and, finally, treatment. The work, as a whole, is well done, but the statements regarding the clinical value of alcohol, in the light of present knowledge, constitutes a larger amount of more arrant nonsense than we have read in a similar amount of space for many a day.

A NEW SIGN OF AORTIC NARROWING.

M. Lemoine has observed two cases in which there existed dilatation of the infundibulum of the aorta, there being a narrowing below attended by insufficiency. The clinical signs, which are new, he describes as follows (*Bull. Med. du Nord.*): The classical systolic souffle exists and, in addition, a presystolic rolling sound which increases as the patient passes from repose to action. While scarcely perceptible in the first instance it increases considerably after a rapid walk and presents its maximum of intensity between the third and fourth intercostal spaces of the right side, and consequently a little lower than the point of election for determining sounds of the aortic valves. In the first case observed by the author, a post-mortem examination confirmed the diagnosis.

PERISCOPE.

THERAPEUTICS.

THERAPEUTICS OF PULMONARY GANGRENE.

In view of the unsatisfactory status of the present therapeutics of pulmonary gangrene, Dr. Hewelke proposes the injection of antiseptic solutions through the chest-wall into the gangrenous part of the lung.

One injection is made daily by means of a syringe armed with a needle about 7 cm. in length. From one to two and a-half cm. of antiseptic solution are used for one injection. An alcoholic solution of thymol 1 to 300 or 1 to 200 seems to be the most applicable.

The author applied this treatment in four cases. Of this number, one died of hæmorrhage before any effect, one way or the other, could be noticed of the treatment. One case was cured in three weeks. In another case all symptoms disappeared in about six weeks. The fourth case went from under observation while it was improving, but was not as yet quite well.

Besides the antiseptic effect, the thymol injection seems to promote emptying of the pulmonary cavity through expectoration, and besides to stimulate the lung tissue to the formation of cicatrices.

As an immediate result of the injection a paroxysm of cough and bloody expectoration occur. But in no case did they excite alarm.

In general we may say that the patients bore the injections well, though they usually complained of their producing a bad taste in the mouth, which, however, did not last long.

The only disagreeable feature of the operation, seems to be the dread with which the patients anticipate it. Instead of decreasing, this dread increased with repetition of the injection.—*Deutche Med. Woch.*

VOMITING TREATED BY BLISTERING OVER THE VAGUS.

Dr. M. J. Kenny writes in the *Brit. Med. Jour.:* Some time since I attended the wife of a farmer, and mother of three children, a healthy well-developed woman, aged 32. I found her in the end of the first stage of labor, head presenting, and making fair progress, but suffering from most distressing vomiting, which came on with each uterine contraction. I was informed by her friends that she had suffered from this distressing symptoms in her previous labors, and that on each occasion the vomiting continued, for several days after delivery, to resist all the drugs employed. I delivered with the forceps, and gave four draughts, one every half-hour, containing hydrocyanic acid, bismuth and opium, but without the smallest effect. I then applied a strong fly blister, one and a-half inch by half-an-inch over each pneumogastric nerve at the anterior border of the sternomastoid. In four hours the vomiting entirely ceased, and did not return.

I believe in cases of persistent vomiting, due, as in the case above recited, to reflex causes, and which very often cannot be controlled by medicine taken by the mouth, blistering over the vagus might be more generally tried with advantage.

METHYLENE BLUE AS AN ANTIPERIODIC.

From the facts that methylene blue is the most satisfactory stain for the plasmodium malariæ, whether in fresh blood or in dried specimens, and that when injected into the circulation of various warm- and cold-blooded animals, this dye stains the red corpuscles, and especially colors the nuclei of nucleated red blood disks, Guttmann and Ehrlich (*Berliner klinische Wochenschrift,* September 28, 1891) have essayed to determine whether this substance has any therapeutic action in malarial disease. The scarcity of malarial affections in Berlin, has, so far, permitted experiment upon only two cases—one of tertian, and another of quotidian ague—but the results have been quite satisfactory. In the first case, one and one-half grains of pure methylene blue, in gelatine capsules, were given every three hours, for five doses, beginning ten to twelve hours before the expected chill; in the second case the same dose was given in five hourly administrations, beginning at the same time before the chill. The periodical attacks in both cases ceased within a few days after the beginning of the treatment, but the drug was continued for eight or ten days longer. No unpleasant effects were caused by the drug in either case, excepting in one instance, when mild strangury occurred, after seven and one-half grains were given at one dose. To obviate this, the experimenters administered daily about half a nutmeg, grated—a portion with each dose of the dye—and had no further occurrence of bladder irritation. The urine was stained deep-blue, its quantity was normal or somewhat increased, but albumen or sugar were never found. Fæces contained the coloring matter in reduced form, becoming deeply blue after exposure to the air. These ex-

periments are interesting, and suggest the possible advantage of combining methylene blue with quinine in the treatment of obstinate malarias of the tropics, which, as is well known, are often but slightly influenced by quinine alone.—*Univ. Med. Mag.*

ANTIPYRIN IN HEPATIC COLICS.

In the *Meditzinskoië Obozrenîë*, No. 17, 1891, p. 463, Dr. Abram E. Pombrak, of Romanovo-Borisoglebsk, highly recommends the internal administration of antipyrin as an analgesic in cases of biliary colic. The author details an illustrative case of a stout lady of thirty-six with symptoms of cholelithiasis of six years' standing, the attacks occurring several times a year and lasting for many days. When called to the lady, on the second day of a severe attack, the writer found her suffering from agonizing pain accompanied by vomiting, collapse, and extreme tenderness about the right hypochondrium. For the first four days he tried the treatment by calomel (two grains hourly until liquid stools), morphium (under the skin and internally), amygdalin, leeches, etc. All the measures having utterly failed to afford relief, on the fifth day antipyrin, in ten-grain doses, and natrosalicylate of caffeine, in one-grain doses, were given (in wafers) every two hours. After three doses the pain began to subside; after further five wafers it ceased altogether. On the seventh day the patient was up and about, feeling quite well.

ON DERMATOL, A PROPOSED SUBSTITUTE FOR IODOFORM—ITS USE IN SURGICAL PRACTICE.

Dr. Charles A. Powers, in the *Med. Rec.* writes: In June of the present year Heinz and Liebrecht commended to the profession, for use as an antiseptic powder, a basic gallate of bismuth to which they gave the name "Dermatol."

The remedy is a yellow, fine powder, unaffected by exposure to light and air, and non-hygroscopic. It had been the subject of extensive experimental and clinical investigation at the university in Breslau, having been used in surgical, gynæcological and dermatological practice. It was found to influence the healing process in wounds, ulcers and the like in a markedly favorable manner, and was thought to combine the better properties of iodoform with the decided advantages of being without odor, non-poisonous, and non-irritating. It was recommended for use in all dressings in which we are accustomed to employ iodoform.

In a further communication Heinz gives in detail the causes which led to the experimentation and the manner in which it was conducted. He says, with the truth, that an antiseptic should not only be able to kill germs or restrain their growth, but that it should be free from injurious local or general effect. It should not cauterize or irritate the wound or its surroundings.

Of the dry antiseptics, iodoform alone has thus far been able to prove itself of exceptional value, and to win for itself a permanent place in surgical practice.

He appends a brief comparison between dermatol and iodoform.

a. CONDITIONS IN WHICH DERMATOL POSSESSES ADVANTAGES OVER IODOFORM.

Dermatol.	*Iodoform.*
1. It is not poisonous.	1. It is distinctly poisonous.
2. It is without odor.	2. Its odor is exceedingly disagreeable.
3. It is absolutely non-irritating, it allays irritation.	3. It produces, in many instances, a troublesome dermatitis of the surrounding skin.
4. It can by sterilized by dry or moist heat (this maybe of distinct advantage when gauze is employed).	4. This is not the case with iodoform.
5. It seems, at present, to lessen discharge to a greater extent, and to favor epithelial formation to a great degree than does iodoform.	

b. CONDITIONS IN WHICH IODOFORM$_1$ POSSESSES ADVANTAGES OVER DERMATOL.

Dermatol.	*Iodoform.*
2. There is no reason for believing that it possesses direct effect on tubercular processes.	1. It is at present somewhat cheaper.
3. It is insoluble.	2. Its anti tubercular action seems to be (clinically) fairly well established.
	3. It is soluble in alcohol and in ether.

TUMENOL IN SKIN DISEASES.

Neisser (*Deutsche Med. Woch.*), after prolonged investigation, recommends tumenol as a valuable application for some skin diseases. This substance was discovered by Spiegel, is allied to ichthyol, and like it, is obtained from mineral oils, the name "tumenol" being abbreviated from bitumen and oleum, the former being the source of mineral oils. Occurring amongst the unsaturated hydrocarbons contained in the mineral oils, the impure mother substance is treated with sulphuric acid, when a process of sulphonation under oxidation takes, which results in the production of tumenol—a compound containing two ingredients, tumenol sulphon, and tumenol sulphonic acid. In order to separate these two the tumenol is converted into salts by the addition of a solution of soda, and then extracted with ether as long as the latter continues to be colored. The

ethereal solution then contains the sulphon, the aqueous solution of the sodium salt of the sulphonic acid. The color of the concentrated preparations is black, more dilute mixtures being grey. The solubility in water is considerable, and the odor not offensive. Hitherto Neisser has only experimented with the aqueous solution of the tumenol sulphonic acid, the salts not having as yet been sufficiently tested. The effect of tumenol as a healing application is probably due to its "reduced" action, and also to the readiness with which it can be absorbed, the preparations in use being two tinctures—equal parts ætheris sulph., sp. vini. rectif., and (*a*) water (*b*) glycerine—a powder, an ointment, and a plaster. Tumenol preparations appear most suitable in the treatment of "weeping," moderately severe eczema, of burns of the first and second degrees, and of many forms of itching, whether due to eczema or prurigo. As a surgical dresser Neisser recommends them for both superficial and deep ulceration, for ecthyma due to pediculi, for rhagades, and for scabies. Ulcers of the leg are often rapidly healed. On the other hand, tumenol is no antiparasitic, nor does it affect the patient constitutionally.

THE TREATMENT OF TUMORS AND PLASTIC EXUDATIONS BY OVERHEATING OF THE TISSUES.

Dr. Guirine (*Roussakaia Med.—Journal de Medicine de Paris*, October 25, 1891) proposes the treatment of tumors and plastic exudations by the super-elevation of the local temperature. The overheating is accomplished with a temperature exceeding that of the interior without the production of burns. In this way there is produced a degeneration of the tissue exposed to the heat. The author has treated a young girl afflicted with a tubercular lymphadenitis of the neck, which has given place to suppuration and cicatrization Hot poultices were applied over a salve of white precipitate, and changed once during the day. After about four months of treatment, the tumor had diminished very perceptibly in size, and had become divided into a number of small glandules. The hot applications did not prove in the least painful. After eight months there were left nothing but three small nodules. Fifty centigrammes of potassium iodide were then administered three times a day to dissipate the deeper infiltrations. After ninety-eight days of treatment the recovery was complete.

In another patient afflicted with hard cancer of the neck, the application of heat twice a day diminished by one-half the volume of the tumor, which was divided into many nodules. With the suspension of the treatment the regression of the tumor ceased. The treatment was terminated by a surgical operation.

The author has further seen beneficial results from the application of overheating to tertiary ulcers of the legs and of the hands, and in one case of purulent pleurisy. The action of the remedy is good also in the old affections of acne vulgaris and psoriasis, the hypertrophies of lymphatic glands, chronic rheumatism, etc.

The resorption of tissues and exudates is favored by applying along with the hot dressings solutions of chloroform, ethyl bromide or chloride, balsamic oils, and other substances which dissociate the fats.

MEDICINE.

LYMPH TRACTS AND LYMPH CIRCULATION OF THE SKIN.

Kromayer (*Donats. f. prakt. Derm.*, No. 9, November, 1891) has investigated the lymph system of the skin, and believes that there is a special and completely close system of lymphatic vessels in the papillary layer of the cutis; that this lymphatic system is one of the chief paths in which affections of the skin spread, and one of the chief reasons why most of these affections are superficial. He does not believe that any excessive transudation from the blood vessels can be compensated by absorption through the lymphatic system.—*Brit. Med. Jour.*

ABNORMAL AND SUPERNUMERARY MAMMÆ.

T. J. McGillicuddy (*N. Y. Med. Rec.*, October 10, 1891) describes ten cases of abnormality of the breast: (1) Woman aged 26; left breast only half the bulk of the right. (2) Woman aged 24; at the third month of her second pregnancy the axillary glands filled with milk; a brown areola was detected in each axilla, but no nipple; after labor the flow of milk gave great trouble, staining and soaking the clothes. (3) Woman aged 19; four days after her second labor a free discharge of milk took place, the milk issuing from two large and several small holes in the left axilla. (4) A single lady aged 26; a large supernumerary breast extended from the seventh to the ninth rib on the right side; the abnormal and the two normal breasts all hypertrophied when the

patient was 24 years old. (5) A female infant aged 7 weeks; a large nipple over the sternum, midway between the normal mammæ, and on a slightly higher level; this position is very rare. (6) A single, delicate, neurasthenic woman aged 26; breasts absent, nipple alone existing, as in a man. (7) girl aged 18, single; when 13 years old it is believed that she received a blow on the right breast; shortly afterwards the breast began to develop rapidly, until it reached the size normal in a young woman of 20; the other breast remained undeveloped. An eminent surgeon believed that this condition represented Paget's disease, and advised removal of the breast; at present the breasts are normal and of the same size; menstruation is regular and there is no disease in the sexual organs. (8) A man, aged 46, has a supernumerary mamma, as large as a normal breast of a young woman, on the posterior aspect of the left thigh, just below the gluteal fold; it appears to have been noticed at birth; its lobular structure can be distinctly determined on manipulation; on its surface are large blue veins, but there is no areola on the skin and the nipple is perfectly smooth. (9 and 10) Cases of supernumerary nipples in the male.—*Brit. Med. Jour.*

STATUS EPILEPTICUS.

This was the subject of a paper read by Drs. Trowridge and Mayberry at the recent meeting of the Americam Medical Association at Washington. It commences with an expression of regret that in a recent systematic treaties on medicine it should have been stated that as regards the immediate danger from the paroxysms the prognosis is always favorable. The authors go on to state that comparatively little consideration has been given to the condition outside asylums, but it does not seem to have to occurred to them that therein may lie an explanation of the fact—the inference of course being that the condition occurs but rarely outsids asylume. In other words, as they themselves state in their conclusions, the status epilepticus is to be regarded as the climax of the neurosis. The paper gives particulars of several cases treated by the authors. They consider that the condition consists of two stages—a convulsive one and a comatose one,—the latter being occasionally replaced by a period of maniacal excitement; and that the condition is not accounted for by any demonstrable coarse lesion, and is likely to end fatally. As regards treatment, general anæsthetics, like chloroform and ether, they regard as of only temporary utility, but they may be administered with advantage where exhaustion is imminent, or while waiting for the action of some other remedy which has been given. Bromide and chloral, morphine, nitrate of amyl, and sulphate of atropine are unsatisfactory; but they are of opinion that considerable reliance may be placed upon the hypodermic injection of hydrobromate of hyoscine or hydrobromate of conine combined with sulphate of morphia.—*Lancet.*

ON THE INFECTIOUSNESS OF INFLUENZA.

Dr. H. Poole Berry writes in the *Lancet* as follows: In various articles and reports which have recently appeared in the medical journals with reference to the spread of epidemic influenza, the writers seem to be quite satisfied that this takes place by infection or contagion from person to person. In deference to the numerous high authorities who hold this opinion, I feel bound to admit it as substantially true; but I think there are very many who have had a large experience of the recent epidemics in the less densely populated parts of the country who will agree with me in thinking that, if it be true that the disease does spread from person to person, nevertheless it certainly does not spread by *direct* infection like scarlet fever, measles, smallpox, whooping-cough, etc., but that the infection must take place by some *indirect* means, just as typhoid fever and cholera are known to spread by infection indirectly. In no other way can I possibly reconcile the facts that I have observed, the manner in which the disease has first attacked certain localities, and the way in which it has subsequently spread. I am forced to such a conclusion by the following reasons.

1. Granting that the disease spreads by infection and infection only, then it must be admitted by all, I think, that it is the most virulently infective disease which we know. By this I mean that either a vastly larger number of people are liable to be attacked by this infection, or that the infection itself is much more readily communicable than is the case with any other infectious diseases which occur amongst us. Numerous instances, however, must, I think, be present in the minds of most of us in which isolated cases have occurred unaccompanied by the development of the disease in those who were in immediate contact with patients suffering from the malady. I need, I think, only allude to one or two such instances in my own practice, feeling confident that these will readily recall in the minds of others a similar

experience: (*a*) In the epidemic of 1890, a young man came from London to his home here, developed typical symptoms of influenza the next day, which ran the usual course, and none of the others in the house were attacked. (*b*) Last autumn, when the disease was not epidemic, isolated cases occurred here, irregularly scattered, cropping up from time to time, and an epidemic did not result till the spring of this year. We had this disease, then, present amongst us last autumn, this disease which is capable of spreading like wildfire through a community, and yet no widespread epidemic occurred. (*c*) In my own house, my groom had a typical attack in the beginning of February, 1891, and, with no attempt at isolation, none of the rest of my household suffered at that time, though in the middle of April I had it myself, followed a fortnight later by my cook (though the incubation period is stated to be only two or three days). This showed that two of my household, at any rate, were liable to be attacked, though we escaped when the infection was in the house in February. (*d*) In another house this year, one case commenced on Jan. 7th, another member of the family was attacked on May 5th, three servants were struck down almost simultaneously on May 26th, and on July 6th another member of the family had the disease. When the disease was present in the house, and no isolation was attempted, if the disease be so very readily communicable, why did they not all have it about the same time?

2. During the last epidemic, I especially noticed that in the villages around here some few cases of influenza were present for from seven to ten days before the great bulk of the cases occurred; that is to say, the disease was present in a particular village for a few days, when suddenly a little later a large percentage of the villagers were almost simultaneouly attacked. Why should the infection smoulder for a few days amongst a few people, and then suddenly flare up, and the whole village, as it were, be then *almost suddenly* struck down?

If those who maintain that the disease spreads by infection will admit at the outset that it does not spread directly from person to person like scarlet fever, measles, etc., but by some indirect means which exist outside the human body, then I think we may admit their theory, the ground for discussion and discovery will become clearer, and all must set to work to find out what is the manner of the indirect means by which the infection spreads. This is of the utmost importance from a preventive point of view, for it has always struck me as savoring of the ludicrous to endeavor to prevent an infection—which is known to rush across a continent in a fortnight or so, numbering its victims by thousands—from spreading by attempts at isolation, from the garret to the ground floor. Whereas, if we can discover the manner in which the infection spreads, or the conditions under which it multiplies, then there is a possible chance, at any rate, of finding out some means of holding it in control.

PERIPHERAL NEURITIS IN CANCER.

Dr. Auché concludes a work on the existence of neuritis in cancerous subjects, in the *Revue de Médicine*, October, 1890, as follows; 1. Neuritis can develop, and in fact often does develop in the course and under the sole influence of carcinomatous affections. 2. The situation of the neuritis is very variable, but in general the nerves are the more altered the farther they are away from the nerve-centres. 3. These neurites are in relation with clinical symptoms which one must know to search for in such cases. 4. They are probably due to nutritive troubles and to alterations of the fluids and tissues which take place in the cachectic period of cancerous tumors.

SYPHILITIC HYSTERIA.

Dr. A. Fournier has recently, (*Gazette hebdomadaire de médicine et de chirurgie*) had a patient suffering from hysteria whose origin he attributed to syphilis. The patient was a sailor, twenty-four years of age; in his infancy he had had croup and scarlatina, at fourteen years of age he had typhoid fever, and during his nineteenth year had indulged in alcoholic excess. His father had been killed in an accident; his mother was alive and well. The patient contracted syphilis in December, 1890, and two hard chancres appeared on the penis. Owing to negligence in treatment, mucous patches appeared in May, 1891. In August the patient began to feel stupid and heavy in the limbs; at the same time he began to manifest emotional symptoms and would secrete himself for hours to avoid being ridiculed. One night towards the end of August he was awakened by a desire to urinate; on arising from his bed, he fell down and was unable to move. He retained consciousness, but could not speak, though he gave vent to an incessant inarticulate cry. At the same time the left side of his face and body became paralyzed. In September an iritis of undoubtedly specific origin appeared and the patient began to be troubled with severe headaches at night.

All these symptoms were improved by specific treatment. The patient was last seen in November. He then appeared stupid; the emotional symptoms remained. He complained of a constant pain over the left parietal region. The paralysis of the left arm and leg had partially disappeared, and there was a well-marked sensory hemi-anæsthesia over the left side of the body. Fournier believes that the hysteria had syphilis as its ætiological factor, as all other modes of origin were eliminated by the patient's history. There was no evidence of alcoholism, nervous shock, traumatism, or general or infectious disease recent enough to be assigned as a cause for the hysterical feature of the case. Previous to the patient's advent to the second stage of syphilis it had been impossible, Fournier added, to discover any symptom that could lead one to suspect hysteria.

SURGERY.

OPERATION FOR INTRA-CRANIAL HÆMORRHAGE.

Dr. Stimson showed, at a recent meeting of the New York Surgical Society, a patient, forty years of age, who some weeks before had been, in the course of a quarrel, struck on the head with a club. When first seen he was found to have a marked irregularity at the junction of the parietal bone with the squamous part of the temporal on the left side. Weakness of the right leg with complete paralysis of the right arm developed—it is not stated how long after the accident,—and his vocabulary was reduced to "Yes" and "No," although he could make voluble use of expletives. A diagnosis was made of intra-cranial hæmorrhage following injury, and five or six days after the injury was inflicted he was operated on. There was found to be a fracture of the temporal bone above the ear, but no depression. A fissure ran backwards over the parietal border. No blood was found between the bone and the dura, but the latter was dark in color, and no pulsation was observed in it. On opening it a large clot was found in the subarachnoid space extending back a considerable way. An ounce and a half in all were removed and the flap sutured. There was no immediate improvement in the patient's condition, but the paralysis gradually passed away and the ability to talk returned, although there was still evident impairment of this faculty. The case is a very important one, and its progress is very suggestive. Apparently operation could not be undertaken at once, as the question of possible homicide was pending, but there seems little reason to doubt that early operation in such a case would be followed by rapid recovery. Even after five or six days, the amount of restoration obtained by the operation must be gratifying both to the patient and the surgeon, and it will no doubt become greater as time goes on. One curious thing about the case, is, that no mention is made of fits of any kind, which we should have expected as a result of a subdural hæmorrage such as was present.—*Lancet.*

ON THE METHODS OF STRETCHING OR EXCISING A PART OF THE INFERIOR DENTAL, LINGUAL, AND SUPERIOR MAXILLARY NERVES FOR EPILEPTIFORM NEURALGIA (TIC DOULOUREUX).

Dr. W. J. Walsham writes, in the *Brit. Med. Jour.:* in the article on the various surgical procedures, devised for the cure or relief of trigeminal neuralgia—"tic douloureux"—lately published in the *Journal,* Mr. Horsley in speaking of the operation for stretching or excising a portion of the inferior dental or lingual nerves by the incision through the mouth, states that this operation may "now be said to be very rarely practised." I was surprised to read this, since it is an operation I have performed very frequently during the last twelve years, and I have come to regard it as the simplest, the safest, and the best of the methods of exposing those nerves. Mr. Horsley says, "The great objection to such an operation, is the certainty of the wound becoming septic, and the consequent inconvenience and danger to the patient, not only from the danger of local necrosis, but of general infection." Seeing that the wound communicates with the mouth, I imagine it cannot be denied that it may become septic, but at the same time I can affirm, from an experience of a very considerable number of these cases, that it heals up perfectly in a few days, and generally by the first intention. I have never seen any general infection follow, and in only one case was there suppuration and local necrosis. But this happened to one of the first patients on whom I operated in this manner, and I attributed it rather to my then inexperience of the operation, and consequent unnecessary disturbance of the parts in exposing the nerve, than to any defect in the operation itself. Moreover, my experience of wounds in general about the mouth is, that, as a rule, they heal exceedingly well. I do not think,

therefore, that any fear of septic trouble, local or general, need deter us from choosing this operation, if in other respects it appears superior to others that have been proposed or performed. That it is superior I claim for the following reasons: (1) That there is no external wound or disfigurement whatever; (2) that no muscle or other important structure is divided; (3) that no removal of bone is necessary; (4) that the parotid gland and the articulation of the jaw are not interfered with; (5) that the exposure of the nerves is all that can be desired; (6) that the wound heals readily in a few days, and that the patient, as a rule, may be said to be perfectly convalescent from the time that he recovers from the anæsthetic.

There are some points, however, to which it is important to attend in performing this simple little operation. 1. A clean and free incision should be made through the mucus membrane to facilitate rapid healing. 2. The internal pterygoid should be separated from the bone without unnecessary bruising; and (3) care should be taken not to detach the periosteum from the jaw. As an example of the simplicity and safety of the operation, I may mention the case of a patient on whom I have operated some five or six times through the mouth. I first stretched his inferior dental nerve ten or twelve years ago. He has perfect immunity from pain after each operation; on the last occasion but one, for about eighteen months. On each recurrence of the neuralgia he comes into the hospital, has his nerve stretched, leaves on the second or third day after the operation, and is thus only incapacitated for business for a few days.

I have read over the steps of Mr. Horsley's operation very carefully, and am acquainted with the operations to which he refers; but I confess that after reconsideration of the subject, it still seems to me that the incision through the mouth is by far the best operation. I make this communication since it seems to me a pity that so simple, so safe, and so efficacious a procedure should fall into disrepute.

I have a word or two to say on the method of stretching or excising the superior maxillary nerve, and removal of Meckel's ganglion. In the few instances in which I have operated, I have reached the nerve and ganglion by working through the antrum, chipping away the lower wall of the infra-orbital canal, and trephining the posterior antral wall. I have had no difficulty with regard to the healing of the antral wound. It seems to me that when the periosteum is separated from the orbital floor, and the upper wall of the infra-orbital canal is attacked, there must be some slight risk of injury to the contents of the orbit; whilst, moreover, the antrum may still be opened, but in such a position that it would there be impracticable to obtain a dependent drain.

THE BURIED SUTURE.

In an editorial in the *North American Practitioner*, the advantages of the buried suture are given as follows:

1. It is a permanent suture.
2. It is a suture which does not invite sepsis, as the skin suture does.
3. It is less painful than the skin suture.
4. It produces more perfect coaptation.
5. It is followed by less scar.
6. It is the ideal suture.

From this study it would seem that the use, except in exceptional instances, of the skin (temporary suture), is as irrational as the use of the temporary ligature.

OBSTETRICS.

MATERNAL IMPRESSIONS.

This subject seems to be perennial in medical literature. Dr. Ballantyne and other modern authorities have given reasons why maternal impressions should be taken into account when the causes of monstrosities are under consideration. A paper on a suspected case of maternal impressson was published in a recent number of the *Centralblatt für Gynäkologie*. Dr. Wolff, of Wilhelmsburg, was consulted in October by a patient recently confined, about a malformation in the child. There was defective development of the middle, ring, and little fingers of the left hand, so that the corresponding metacarpal bones each bore a single ill-formed phalanx, with a rudimentary nail. The rest of the child's body was free from any deformity. None of the infant's relatives appear to have been subject to any kind of deformity. The mother informed Dr. Wolff that in the second month of pregnancy she was greatly distressed by seeing a woman who had lost nearly all the fingers of one hand at a fire. There was also ugly scars on the face and neck, but the mother could not help dwelling for months on the injured, fingerless hand. We must not overlook the possibility of coincidence, as burnt hands are not rare, nor is imperfect development of the fingers extremely infrequent. Again, some relative may have had a similar deformity, which his or her relatives had overlooked. Every medical man who has made extensive clinical

researches is aware how very little people know about their nearest relatives. Professor Bertram Windle has recently written on teratological evidence as to the heredity of acquired conditions, and shown how polydactyly at least tends to be hereditary. There are several other questions to be considered before the doctrine of maternal impressions can be established as a sound, scientific theory. Amniotic bands certainly damage many parts of the fœtal body, and the fingers seem particularly exposed to injury from that source. The fœtus is not free from disease of its blood-vessels, which may arrest nutrition and development, especially at the extremities. Lastly, the supporters of the maternal impression doctrine cannot show how psychical influences in the mother may influence the development of the child. Such influences may exist, but, as a rule, monstrosities can be traced to more definite sources.—*Brit Med. Jour.*

FORECASTING THE SEX OF THE CHILD BEFORE BIRTH.

Dr. R. Ross says in the *Lancet* that for many years he has been in the habit of successfully determining the sex of the child from the position in which the mother describes the fœtal movements to be most marked and constant. Most women can, but some cannot, differentiate the locality. In those who can he finds the following rule applies. If the fœtal motions are chiefly and most intensely felt on the left side, predict a male ; if on the right, a female. The following cases from his note-book :

1. S.	Chief site of fœtal motions	left side.	Male birth.	
2. C.	do	do	do	
3. M.	do	do	do	
4. Mac.	do.	do	do	
5. S.	do	do	do	
6. B.	Chief site of fœtal motions	right side.	Female birth.	
7. Sm.	do	do	do	
8. St.	do	do	do	
9. B	do	do	do	
10. Me.	do	do	do	
11. Ma.	do	do	do	

GALEGA AS A GALACTAGOGUE.

Carbon de la Carrierre says: (*Arch. de Toc. et de Gyn.*, August, 1891) Goat's rue is an almost forgotten drug at the present day, although at one time it had a certain reputation as a galactagogue. The author believes that it deserves to be reinstated, as, according to his experience, it has a decided effect on the mammary gland, increasing deficient and restoring suspended secretion of milk.

All physicians have met with cases in which, in spite of every hygienic precaution, the milk becomes less in quantity without any appreciable cause. Poultices of the leaves of the castor-oil plant and faradization of the breast do not give the desired result. Phosphate of calcium, extract of malt, and Bordeaux are often administered. Galega is a useful adjuvant, and, even when used alone, gives excellent results. It is perfectly innocuous, is a stimulant to digestion, and is slightly diuretic in its action.

The aqueous extract is the one to be preferred. One to five drachms should be given daily in divided doses. The amount may be increased if necessary. The drug takes effect in a few hours, but must be persisted in for at least ten days in order to secure permanent results. It may be administered with distilled water and simple syrup, or in mucilage in the form of pills. Fennel and calcium phosphate may be associated with it to advantage. An especially efficacious formula is the following:

℞ Aqueous extract of galega,
Lactophosphate of lime,
Tincture of fennel.....āā ʒij; gr. 40
Simple syrup..... ʒxij; ʒvi.

Four to eight tablespoonfuls a day in water, beer, or milk.

GYNÆCOLOGY.

LACERATION OF THE VAGINA.

Piering (*Centralbl. f. Gynäk.*, November 28th, 1891) speaks, not of the tearing away of the vagina transversely from the cervix, but of longitudinal lacerations confined to the vagina itself. Most authorities attribute recto-vaginal fistulæ to direct perforation by instruments and pieces of bone, or to imperfectly healed lacerations of the perineum. Dr. Piering describes a case where the vagina was torn during spontaneous labor. The patient was a primipara, aged 41 ; the soft parts were very rigid. Instruments were not needed, but the head was delayed at the perineum, so that it was thought advisable to make an incision one inch long in the tough inelastic perineal tissues, on the right side. The parts were watched during the next pain, when a gush of blood escaped from the rectum, the right hand and part of the forearm of the fœtus appearing out of the anus. The arm was replaced, and the child was born without any further damage to the perineum. The tissues around the laceration were much bruised, and union by first intention could not be expected. The incision in the perineum was found to be no longer than it was when made by the operator. The cervix was not lacerated. After thorough disinfection of the parts, the vagina was plugged

with iodoform gauze. On the third day the bowels acted no fæces came through the vagina. During childbed there were two attacks of fever, which disappeared when the surface of the wound was painted with tincture of iodine. When the patient was discharged, a firm and perfect cicatrix had formed; it could not be distinguished on the rectal side.

RAPID EXPLORATION OF THE UTERINE CAVITY.

The report of the removal of the ovaries for persistent uterine bleeding, by Dr. Farcourt Barnes, is received with considerable surprise by J. F. W. Ross (*New York Medical Journal,* October 24, 1891). Dr. Ross is in the habit of forcibly dilating the uterus under these circumstances, and exploring the cavity of the uterus with his little finger. He has yet to meet with the first case of damaged appendages produced by rapid dilatation and exploration. The procedure must be carried out on strictly antiseptic principles. The vagina and cervix should be thoroughly irrigated with a sublimate solution; instruments are to be taken directly from boiling water, and rendered cool enough to handle. The Goodell dilator is the best. The cervix is gradually dilated, and when the limit of the instrument (an inch and a half) is nearly reached, the blades are allowed to fall together again, so as to relieve the tension for a moment and restore the circulation of the part.

When the limit is reached this is also done, and the blades are again separated, so as to make the dilatation as complete as possible. The dilator must be passed beyond the interal os. When this is accomplished the little finger is readily passed into the uterus, and its cavity completely investigated. The uterine cavity is packed with iodoform gauze, and the vagina is filled with the same material. The patient is kept in bed for several days, and the gauze is removed in forty-eight hours. Cleansing douches are then given. By this treatment he has diagnosed cancer of the fundus, sloughing intrauterine fibroids, fungus endometritis and retained placenta. He is firmly convinced that cases of obscure hæmorrhage from the uterine cavity are, in the main, due to the presence of small, almost unrecognizable fibroids. The practice of making irritant applications —such as carbolic acid, iodine, etc.—after dilatation and exploration to be condemned. Gradual dilatation by tents or bougies is not advised.—*Univ. Med. Mag.*

THE TREATMENT OF CHRONIC OVARITIS.

A. J. C. Skene (*Medical News,* June 13. 1891). Many of the cases treated by abdominal section are not much, if at all improved. The cases cured are those operated on when near the menopause; those improved are generally such as have suffered from complicating affections; for example, dysmenorrhea; while the unimproved are the younger subjects in whom the disease was uncomplicated. The indications for treatment are both general and local. The indications for general treatment are to lessen the blood supply and relieve pain by correcting the deranged innervation. This, in the early stage, demands rest in the recumbent position. At the same time general exercise should be advised, either by massage or by gymnastics in the reclining position. The condition of the digestive organs should be carefully watched and relieved by small doses of mercury and a laxative. The saline laxatives are the best. To relieve pain and lessen the hyperæmia the bromide of sodium and fluid extract of hydrastis canadensis are by far the most potential agents; they are given in combination--twenty to thirty grains of the bromide and ten to twenty minims of the hydrastis, three times a day, until the physiological effects of the bromide are noticed in a mild degree.

Sometimes the bromide fails, even in larger doses, to relieve the menstrual pain. In this case ten grains of salicylate of sodium and five of antipyrin, given between meals, answer for some time; others, more especially those markedly debilitated, do better on full doses of aromatic spirits of ammonia, camphor and chloric ether, with small doses of cannabis indica. In the unmarried local treatment should be avoided. Hot sitz-baths, counter-irritation and hot vaginal douches comprise about all that should be employed in young women. In married women any complicating disease should be treated locally. In addition, applications which will relieve the tender and hyperæmic ovaries are applicable. A small tampon, saturated with equal parts of tincture of belladonna and glycerine, applied behind the cervix and permitted to remain forty-eight hours, is useful, and after its removal a hot douche. These are continued for five days, and are followed by an application of tincture of iodine to the vaginal vault. Geod effect has been obtained from the sulphichthyolate of ammonium, five parts in ninety-five of glycerine, applied in the same way as the belladonna and glycerine. The general and local treatment thus briefly outlined gives relief to the more pronounced symptoms.

The pain becomes less and also the tenderness. The general health improves and the pelvic congestion subsides. From this point tonics and laxatives may still be required, but alteratives are also indicated. Iodine and mercury are the chief agents. Small doses of bichloride of mercury, with chloride of iron, when iron is indicated, followed by syrup of the iodide of iron, in doses as large as can be borne, may be administered. These can only be used when the bromides are given up. In place of the bromides, sulphonal is of great value to promote sleep. The treatment is necessarily a long-continued one and requires patience and careful watching.—*Univ. Med. Mag.*

PÆDIATRICS.

DIPHTHERIAL INFECTION OF TRACHEOTOMY WOUNDS.

Dr. Spronk, of Utrecht, (*Centralb. f. Allg. Path. u. Path. Anat.*, 1892, No. 1) has discovered in the case of three children who had been tracheotomised for diphtheria a condition which has not hitherto been described, but which he thinks is far from rare. This consists in an inflammatory œdema of the subcutaneous and fatty tissue around the tracheotomy incision, caused by the invasion of diphtheria-bacilli. He points out that in ordinary diphtheria the bacilli are confined to the epithelial surface and the false membrane, and never penetrate into even the uppermost layers of connective tissue so long as the mucous membrane is free from necrosis. Nor are the bacilli ever found in the internal organs and blood of infected individuals. Nevertheless it has been shown experimentally that these microbes can multiply in the subcutaneous tissues, especially of some animals, guinea-pigs for example. The cases he examined had died a few days after tracheotomy, and although the wound itself was free from membrane, and looked healthy, yet there was a more or less widespread diffuse œdema, without any change in the superjacent skin. This œdema was obviously inflammatory, but there was no necrosis. In two cases it occurred not only in the vicinity of the wound, round the trachea and in the intermuscular tissue, but extended for some distance over the chest and upwards to the supra-clavicular regions. He found by tube-cultures that the serum taken from different parts of the œdematous area contained abundant bacilli, which were almost as numerous at a distance from the wound as near to it. The possibility that they may have multiplied after death was slight, seeing that these organisms require a temperature of at least 20 C. to grow. Other bacterial colonies were produced from the serum, but in one case this yielded almost a pure culture of Klebs' bacilli, and the capability of these organisms to cause this type of inflammation was proved experimentally. Dr. Spronk lays especial stress on the fact that, although of course the infection takes place through the tracheotomy wound, yet its margins appeared natural. This he ascribes to the use of iodoform and the short time that elapsed between the operation and death. The importance of the discovery lies in the additional risk of the rapid absorption of the toxine produced by the bacilli when these are lodged in the connective tissue.—*Lancet.*

NEW ANTHELMINTIC, SANTONINOXYME.

Coppola (*La Union Médicale*, March 26, 1891.) thinks that he has discovered in santoninoxyme, a derivative of santonine, a safe and reliable substitute for this favorite anthelmintic. It was found that animals in which epileptiform convulsions were produced by santonine were unaffected by even large doses of santoninoxyme. Its therapeutic action is sure and certain, and its administration is not followed by any secondary disagreeable phenomena. Santoninoxyme is employed in the same manner as santonine, with the exception that the dose is three times as large.

A NEW TREATMENT OF DIPHTHERIA.

Catuffe, in view of the difficulties frequently encountered in attempts to swab the throat in diphtheritic children (*Bulletin Medical*), thinks that it is better to abandon the use of collutories, and to substitute therefor a remedy which is both sialogogue and antiseptic. His procedure is as follows:

During the day inunctions of fifteen to thirty grains of mercurial ointment are to be made every hour; and, at night, every two or three hours, at the sites of election (the axillæ, internal aspect of the thighs). At the same time frequent washing out of the mouth with a solution of chlorate of potassium, together with a general treatment.

By these means, the author claims to have obtained excellent results, having observed neither albuminuria nor stomatitis. In all the cases salivation was quite abundant.

To Stupefy Bees, some apiarists are in habit of burning in the hives ammonium nitrate, which thereby is converted into laughing gas (N_2O).

HYGIENE.

RECENT EXPERIMENTS WITH THE PNEUMOCOCCUS OF PNEUMONIA AND ITS TOXINE AND ANTITOXINE. THE POSSIBILITY OF CONFERRING IMMUNITY IN ANIMALS, AND EVEN IN MAN.

G. and F. Klemperer have published a memoir in which are detailed some important recent experiments, the practical outcome of which may possibly be of some real therapeutic importance.

The directing idea which guided these German investigators in their experiments was the following: It is known that in most cases pneumonia after having, during from five to seven days, caused grave general symptoms, terminates abruptly by crisis. In the space of a few hours, the temperature falls to its normal level, and even below it, the pulse becomes slower and firmer, and the patient experiences a striking amendment. Now at this moment there has been little or no change in the state of the lungs, which still remain infiltrated with fibrinous exudation, nor in the properties of the pneumococci, which are found in great numbers in the sputa, and retain all their virulence, as can easily be proved by inoculations of animals.

The pneumonic crisis, then, does not depend on any change in the state of the lungs, or in the microbes which have caused the infection. To what, then, are we to attribute it? Only one explanation is possible; the crisis is due to the products of secretion of the pneumococcus, which, by their accumulation, modify at a given moment the soil on which the microbes develop.

In their experiments made on hares, the Klemperers early observed that any nutritive substance which had served as a culture medium for the pnemococci, even if it had been separated from the microbes by filtration, might confer on the animal immunity against the pneumonic infection. The power of this vaccine may be augmented, both in rapidity and intensity of action, by subjecting the liquid for two or three days to a temperature of 41° C., or during two or three hours to a temperature of 60° C.

They then obtained experimental proof that the blood-serum of a hare "vaccinated" against the pneumococcus, may cure the pneumonic infection; it suffices to inject this serum under the skin or into the veins of the infected animal. An intravenous injection of eight cubic centimetres of serum of an animal rendered refractory, practised twenty-four hours after the infection produces a gradual fall in the febrile temperature, and hastens the cure of the animal.

As will be seen, these experiments strikingly resemble those of Behring and Kitasato, who lately announced that the blood-serum of animals rendered refractory to tetanus and diphtheria, is capable of curing other animals of these diseases.

In another series of researches devoted to the study of the cause of the curative action of the serum of vaccinated animals, the German pathologists found that the pneumococcus when introduced into the body of an animal gives rise to the production of a *pneumotoxine* which may be isolated. This pneumotoxine produces a febrile reaction of several days' duration, after which they have noted in the fluids of the animal, another substance, *anti-pneumotoxine*, which has the property of neutralizing pneumotoxine.

The blood-serum of an animal on which immunity has been conferred, contains anti-pneumotoxine, and it is this which seems to forward the cure of the pneumonic infection. In the blood-serum of patients affected with fibrinous pneumonia, they have also found pneumotoxine and anti-pneumotoxine, the first, chiefly during the febrile period of the disease, the second, after the crisis. They claim to have cured the pnemonic infection in hares, by injecting in these animals blood-serum taken from a pneumonic patient after the crisis.

After being assured by experiments made on themselves, that man may support with impunity and without any local and general reaction injections of the serum of animals rendered refractory to Fraenkel's diplococcus, the pathologists above mentioned ventured to experiment clinically, with therapeutic intent, on some patients, affected with pneumonia. Although these trials covered only six patients, the result has been encouraging. In fact, in all these patients, a hypodermic injection of four to six cubic centimetres of serum was followed at the end of from six to twelve hours by a considerable fall in the temperature with slowing of the pulse and respiration.

These experiments are especially noteworthy in that they so strikingly confirm the almost simultaneous and independent experiments of Emmerich and Fowitzky, who claim that they have conferred immunity on the hare by means of hypodermic injections of attenuated cultures of the pneumococcus; but this immunity, they say, is incomplete, and the extract of the organs of the animal has but an incomplete curative action. On

hares infected by pneumococci, *per contra*, full immunity is obtained by intravenous injections of a culture having its entire virulence, but largely diluted. The liquid obtained by crushing and expression of the organs of an animal thus rendered refractory exercises on the pneumonic infection a sure curative action when it is injected under the skin into the abdominal cavity, and especially into the veins of the infected animal.

Large expectations are being entertained by many enthusiastic workers, that researches akin to those above noticed, now going on in many parts of the world—researches the inspiration to which came from Selmi, Gautier, Bouchard, and especially Koch—are destined to be very fruitful in therapeutic results, and that possibly the physician of the future, armed with his hypodermic syringe and his vial of "antitoxine" will find himself master of any and every infection. However, the disappointment experienced thus far in regard to tuberculin should cause us to entertain such expectations with a degree of caution and moderation.—*Bost. Med. Surg. Jour.*

MEDICAL CHEMISTRY.

EUCALYPTO RESORCIN.

This is the name given by Barbey, in the *Bulletin Commercial*, to a reaction product of resorcin and oil of eucalyptus. Resorcin in excess is mixed with oil of eucalyptus, and chloroform is added, and the whole shaken. The clear solution, when poured off, leaves behind a mass of needle-like crystals, having a strong camphoric odor, and which are insoluble in water, but easily soluble in alcohol, ether, and chloroform. This body, on fractional distillation, gives various liquid and solid distillates which have not yet been examined. Naphthol, pyrogallol, and picric acid also give with eucalyptol similar crystalline bodies, all of which have a strong camphoric odor.

QUANTITATIVE ESTIMATION OF PEPTONES.

Riva-Rocci describes (*Centralbl. f. klin. Med.*, November 21st, 1891) a new method, as those hitherto proposed have not been available for clinical work. The greatest difficulty consists in getting rid of the agent employed in throwing down the remaining albuminates, or in estimating the amount of this agent. The author saturates the filtrate from the stomach contents with magnesic sulphate, this salt being used in preference to ammonic sulphate, as it is not decomposed by calcination. Since the magnesic sulphate must be previously dried at 110° C., Riva-Rocci found it necessary to determine the difference in weight between the exsiccated salt at 110° and the calcined salt at 220° when all its water of crystallization has been given off. This amounted to 15 per cent. of its weight. The method consists in estimating (1) the total amount of albumen after it has been precipitated by absolute alcohol; (2) the coagulable albuminous bodies according to Devoto's method; and (3) all the albuminous bodies except Kühne's peptones after they have been thrown down by a saturated solution of magnesic sulphate. The weight of the salt present as ascertained after calcination plus 15 per cent. of its weight is then substracted. The difference between (1) and (3) represents the amount of peptones, and that between (2) and (3) the quantity of hemi-albumoses present.—*Brit. Med. Jour.*

ACETANILIDE AND SALICYLIC ACID.

Dr. Ritsert observed some time ago that the mixture of the above compound with ammonium bromide, known as "antinervin," is remarkable for the fact that the melting-point of the mixture is much below that of its constituents. Mr. H. Prüsse, one of his pupils, has since taken the matter up, and sends a report to the *Pharmaceutische Zeitung*. Acetanilide melts at 114° C., and salicylic acid at 156° C., but antinervin melts at about 80° C. The following are the results obtained from the examination of various mixtures, the lower figures denoting when melting began and the higher when it was complete:—

One equivalent of salicylic acid with	
1 equivalent of acetanilide	82° C.—119° C.
$\frac{1}{2}$ " "	93° C.—141° C.
$\frac{1}{4}$ " "	127° C.—148° C.
$\frac{1}{10}$ " "	139° C.—150° C.
$\frac{1}{100}$ " "	144° C.—154° C.
One equivalent of acetanilide with	
1 equivalent of salicylic acid	82° C.—119° C.
$\frac{1}{2}$ " " "	76° C.— 86° C.
$\frac{1}{4}$ " " "	88° C.—100° C.
$\frac{1}{10}$ " " "	91° C.—104° C.
$\frac{1}{100}$ " " "	107° C.—111° C.

It is evident from these figures that as small a proportion as 1-100th equivalent of either body mixed with the other is capable of materially altering the melting-point, and, obviously, antinervin is as near as possible represented by a mixture of 1 equivalent of acetanilide and a half of salicylic acid.

Two Thousand names of soaps of domestic and foreign manufacture registered at the patent office, are enumerated by the *American Soap Journal and Perfume Gazette.*

NEWS AND MISCELLANY.

THE PAN-AMERICAN MEDICAL CONGRESS IN NEW YORK STATE.

At a meeting of the Medical Society of the State of New York at Albany, February 5, a committee was appointed to co-operate in promoting the interests of the Pan-American Medical Congress. The committee consisted of Drs. S. Walter Suiter, A. Vander Veer, James D. Spencer, Seneca D. Powell, W. W. Potter, D. B. St. John Roosa, and J O. Roe.

AN ARMY MEDICAL BOARD.

Will be in session in New York City, N. Y., during April, 1892, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board, will make application to the Secretary of War, before April 1, 1892, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Further information regarding the examinations, may be obtained by addressing the Surgeon-General U. S. Army, Washington, D. C.

C. Sutherland
Surgeon General U. S. Army.

A Concourse will be held at Rush Medical College, beginning Tuesday evening, March 1, for the purpose of filling the positions of Lecturer on Anatomy, and on Materia Medica, and Therapeutics in the Spring faculty.

The Spring course begins March 31, directly after the close of the regular term, and continues two months with a class of from 250 to 300 students, thus affording the lecturers an excellent opportunity to exercise their skill as teachers.

It is the policy of the College, so far as practicable, to fill vacancies iu the regular faculty from the corps of Spring instructors, Nine of the present members of the regular Faculty have been selected in this way.

The Concourse will consist of twenty minute lectures by each of the applicants before the Faculty, students and local profession, upon subjects pertaining to their branches, which will be furnished by the Professors of Anatomy, and Materia Medica and Therapeutics, a week before the contest.

E. Fletcher Ingalls,
Registrar.

A MORBID VIENNESE CUSTOM.

It appears (says the *Medical Record*) that a somewhat morbid custom exists among the Viennese of having the dead bodies of children and other persons dear to them photographed, and for this purpose the corpse used to be taken to the photographer's studio. The attention of the sanitary authorities having been drawn to the danger of the dissemination of infectious disease by this practice, a decree has been issued by the Austrian Minister of the Interior absolutely forbidding the photographing of corpses in studios open to the public, and the photographing of bodies of persons who have died of any infectious disease by professional photographers, even in private houses. Exception is made of cases in which such photographs may be required for police or medico-legal purposes. In case of persons who have died of non-infectious disease, the corpses may be photographed at the private residence of the deceased, subject to the approval and on the responsibility of the medical official whose duty it is to verify deaths.

MORTALITY OF THE HUMAN RACE.

The annual mortality on the whole earth may be estimated on the ground of recent statistical results at about 33,000,000 of persons, which constitutes an average 91,554 deaths per day, 3,730 per hour, and consequently sixty-two per minute. The average length of human life is thirty-eight years. One-fourth of the human race dies before attaining the seventh year; one-half before attaining the sixteenth year, or in the course of this year. But one person among 10,000 attains the age or 100 years, while one among 500 attains ninety; one among 100 attains sixty. Married people live longer than the unmarried. Among 1,000 persons who have reached the age of seventy years, forty-three belong to the clergy or to the political class, forty to the agricultural class, thirty-three are workmen, thirty-two are soldiers, twenty-nine are lawyers or engineers, twenty-seven are professors, twenty-four physicians. —*Internationaler Phar. General-Anzeiger.*

EUROPHEN.

This Product is formed by the action of iodine upon isobutylorthocresol. It possesses extraordinary value as a dressing in both simple and specific lesions. It has an agreeable odor and is, in all cases, a perfect substitute for iodoform. Europhen has been successfully employed by Drs. Petersen, Seifert, Szoldrski, Eichhoff and others, in the Dermatoses and many Inflammatory and Ulcerative Conditions, and has been given hypodermically in Syphilis. It is supplied in ounces.

PHENACETINE-BAYER.

As an Antipyretic, Analgesic, Anti-rheumatic and Anti-neuralgic, Phenacetine-Bayer is justly regarded as the safest and most effective of medicaments. In Acute, Inflammatory Fevers, Rheumatism, Neuralgia, Migraine, Bronchitis, Pertussis, Phthisis, and all affections in which fever, pain and restlessness, separately or together, are to be combated, it has an admirable influence. For INFLUENZA (or "*la grippe*"), Phenacetine-Bayer with Salol is our best remedy. It is supplied in ounces, in pills and tablets of 2, 3, 4 and 5 grains; and also in pills combined with Salol or Caffeine.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

CONGENITAL PHIMOSIS—THACEITIS—SWELLING AT THE WRIST—FUNGUS GRANULATIONS FROM RUBBING OF TOES—INFLAMMATION OF DELTOID MUSCLE—STRICTURE OF THE URETHRA.

By JOHN B. HAMILTON, LL. D., M D,
Professor of the Principles of Surgery and Clinical Surgery, Rush Medical College, Chicago, Ill.

CONGENITAL PHIMOSIS.

Gentlemen:—We have before us a case of congenital phimosis. There are two or three operations which may be performed for the relief of this condition. Perhaps the ordinary Jewish operation is the best when performed on the infant, but it is hardly applicable to the adult. This consists in the retraction of the foreskin, drawing the prepuce through the slit in the instrument and cutting it off; then there is left the mucous membrane covering the foreskin, which is taken between the thumb and finger and forcibly torn until the crown of the glans is exposed. No suture is required in the case, and there is but little hæmorrhage. That is the Jewish operation of performing circumcision. I have seen it performed several times by those accustomed to it.

In a surgical clinic, circumcision is performed sometimes for concealed chancre, herpetic eruption, or adherent prepuce. In this case we have a congenital phimosis and doubtless we will find the mucous membrane pretty thoroughly adherent to the foreskin. I will now take this instrument—it is in fact a tenaculum having a slit in the handle, and with a forceps I will seize the foreskin and draw it over. The skin is now retracted as much as is practicable, while with the scalpel, you will see that we have made a circular incision, involving only the skin. I now slit back the mucous membrane on the dorsum and expose the corona. In this case I am obliged to apply a ligature to a small vessel, and a few stitches to secure the mucous membrane to the skin.

THECEITIS.

I will now show you two cases of theceitis. The first patient, who is obliged to use the arm a great deal during her daily pursuits, has a swelling just over the middle of the ulna, which is soft and fluctuating, but which as I move the arm seems to come from the sheath of the tendon. It is not very painful, but she complains that during certain times the swelling increases in size. This swelling is undoubtedly an exudate from inflammation of the theca of the tendon, what would be in a joint, a synovitis, but as it happens to be in the sheath of the tendon, it is given a different name—theceitis. It is due to a subacute inflammation of the sheath of the tendon, and on puncturing it with the exploring needle a drop of fluid is seen to exude. There is no particular difference between this form of inflammation of the theca and that of a ganglion, except that the ganglion is circumscribed. This is simply a disease of the tendon sheath, by which an extremely lavish amount of exudate is poured out. It requires rest in order to cure the tendon, general puncturing and allowing the excess of fluid to escape, and the application of a bandage. Tincture of iodine is always useful in such cases. A ferruginous tonic would be extremely desirable in this case.

In the second case the marks of the old fashioned scarificator are visible. It shows its teeth on some occasions. If you notice, we have a swelling here along the tendinous sheaths, which is sometimes due to rupture of the annular ligament. It is not so in this case; but we have an enlarged, thickened sheath. It is really a theceitis or inflammation of the theca of the tendons, and of course it occurs in people who are constantly straining

these tendons to their utmost. We must resort to compression as a palliative treatment in this case, using external application of iodine compresses where the projection is pronounced like it is here. We will use a flat cork pressed over the wrist with a bandage tied above. It is no use to resort to leeching or scarification in this stage of the complaint, as it does no good. By strong compression we can make the swelling disappear. You will notice that the patient is hardly able to extend the finger, that is simply due to an inflammation of the flexor tendons which have made them by forcible contraction overcome their antagonists, the extensors.

SWELLING AT THE WRIST.

You will notice here a swelling at the wrist. You see it often in female laboring people, especially in scrub women. We have the same condition of things that I described to you in inflammation of the theca or sheath of the muscle, only at the tendon you see a fluctuating tumor at this point (illustrating). The treatment for this condition consists in making firm pressure over the affected wrist and the application of an elastic bandage the same as you would apply in a case of varicose veins of the leg. At present it will require a compress and roller bandage.

FUNGOUS GRANULATIONS FROM RUBBING OF TOES.

This man has some fungous granulations of the toes at the point where I place my probe, the fourth toe, and also some commencing between the second and third toes. They are due directly to pressure, and the insertion of any ointment between the toes, or a little sublimated gauze that will keep the toes apart, and the surfaces from rubbing together, will be sufficient to cure them ; at the same time, he should have a boot made large enough so that the toes will not be compressed, but remain separate.

INFLAMMATION OF THE DELTOID MUSCLE.

Our next case is a little boy about 9 or 10 years of age, a Bohemian, unable to speak English, and we are unable to get any information either out of him or his mother. We do know that the little boy has some trouble with his shoulder. With this lack of information we are reduced to the objective symptoms for a diagnosis of the case. It is easy to see that the shoulder hurts him, for he cries when I make even slight pressure against it. There is no swelling directly in the shoulder joint, but the swelling is over the deltoid muscle. I notice further that there has been bruising of the shoulder. As I grasp the deltoid I can feel a thickening of the muscular structure, and a little circumscribed swelling at that point. It is possible that an abscess is in process of formation. I find on inserting an exploratory needle into the swelling that it is solid, and doubtless it has come entirely from a bruise. A lady who comes with the child states that the mother has been seen to beat the child severely, and undoubtedly that is the cause of the trouble. It is simply an inflammation of the deltoid muscle and should be treated with chloroform liniment or something of that sort, and a bandage.

STRICTURE OF THE URETHRA.

All parts covered with mucous membrane are extremely sensitive to the influence of cocaine, much more so than other tissues of the body, hence pretty severe operations can be done on the penis under the influence of cocaine alone without the administration of a general anæsthetic. In this case we will inject cocaine locally. I will first endeavor to locate the stricture, which I find both in the spongy and membranous portions of the urethra. You see that a bougie, No. 17, French, cannot be passed. As a general thing I like to test a stricture with a large bougie because small bougies are apt to form false passages. I prefer to pass in this case a cutting instrument, sliding it over one of the small whale bone guides which I show you. For the membranous portion of the urethra I prefer forcible dilatation either by the instrument I show you, or by the better one of Thompson.
